FINANCIAL CONTRIBUTORS

We thankfully acknowledge the vision and support of Rutgers University and the Thomas A. Edison Papers Board of Sponsors.

This edition was made possible by grant funds provided from the New Jersey Historical Commission, National Historical Publications and Records Commission, and The National Endowment for the Humanities. Major underwriting has been provided by the Barkley Fund, through the National Trust for the Humanities, and by The Charles Edison Foundation.

We are grateful for the generous support of the IEEE Foundation, the Hyde & Watson Foundation, the Martinson Family Foundation, and the GE Foundation. We acknowledge gifts from many other individuals, as well as an anonymous donor; the Association of Edison Illuminating Companies; and the Edison Electric Institute. For the assistance of all these organizations and individuals, as well as for the indispensable aid of archivists, librarians, scholars, and collectors, the editors are most grateful.

A Note on the Sources
The pages which have been filmed are the best copies available. Every technical effort possible has been made to ensure legibility.

PUBLICATION AND MICROFILM COPYING RESTRICTIONS

Reel duplication of the whole or of any part of this film is prohibited. In lieu of transcripts, however, enlarged photocopies of selected items contained on these reels may be made in order to facilitate research.

NOTEBOOK SERIES
NOTEBOOKS BY EDISON

Notebook Series -- Notebooks by Edison
Notebook, N-13-11-22

This notebook was used by Edison during November-December 1913; one entry contains notations by an unidentified experimenter. The entries relate to a sequence of experiments, numbered from 15 to 90, which continue the experiments in N-13-08-14.2. They pertain primarily to the printing and transfer processes involved in disc record manufacture. Included are notes and results from experimental batches of transfers made according to different production schedules, different varnish compositions, or different preparations of the record blanks. Also included are descriptions of the various scrapers used in the preparation of the record blanks. Entry 55 directs Sherwood T. (Sam) Moore that "for present this is our Transfer & Printing Schedules." Another entry describes Charles Dally's "slot screen" experiments, which were intended to improve the quality of the screening of powder for the powder blanks. At the end of the book is an entry on the testing of "Dinwiddie's grafited tracked White Masters." The notes indicate that Walter H. Miller and Ernest C. Richter also assisted in the experiments. Inserted into the book are two loose pages of related notes by Edison. The front cover is labeled "Disc Records." The pages are unnumbered. Approximately 150 pages have been used.

No 15 Schedule

3 Minutes at 500 lbs with steam
Coal. 3 plates —

Many Buds III Has also outer red bud row

One has row red breaks over
nearly the entire circumference

Print 2 head 2 Contact 5 1000 lbs

Last night we tested some 55 Schedule Transfers present — In Ernies room with his speaker All were Very loud + bad RO We were scared —

This morning brot Ernies speaker to Chem room — tested it against our reg here — found it 20% louder —

Also retested some 55 schedules found Surface a RO good most of them better than surface of our standard Double transfer record — Afterwards found trouble in Ernies unit which was probably running over 100 Rev — so RO + surface are good

Also found many record Cut Had died last night in Ernies room

4

Think Double transfer would be OK if cut blank was flat + edges clean

But Edges weld on 1st transfer + stuff Cant Cook out,

67

Take 6 55 Schedule transfers + put another transfer over them using 55 Schedule transfers + punch

Double Transfer —

1 — Cooked on 2nd Trans
2 Cooked Cracked on 2nd — Red both sides
3 Cracked on 2nd transfer — Red both sides
4 Cooked on 2nd " Red - Cracked both sides
5 — Cooked, both sides, Cracked 1 side Second Transfer
6 Wrinkles - NG
7 Cracked both side bigreed only on 2nd transfer
8 Cooked - both sides + only 2nd transfer
9 Cracked, Cooked both side bigreed only 2nd T
10 Cooked both sides, bigred only 2nd Transfer
11 Cracked " " " "
12 Cooked " " " "

This 55 Schedule doesnot make a double transfer on New blank Its a failure Most of red in Center

1/2 OK — Slight Red quad

1/2 OK — slight red

Millers Tracked blank hot + Cold last night on Ernies Spkr + over 100 Rev Wear sounded like a Godd yard + very bad run out due to over 100 apprx + not noticed at the time -

Next day a new print tested on Chem room showed pretty good surface + some RO

This pm printed on Reg Green Double Transfer shows very fine matt scorfade only V V V fault RO both sides —

The Master is Evidently OK as far as general surface is Concerned + Perfectly Satisfactory —

69 —

Use Miller Warm + cold blank in printing Use new blanks Transferred on 55 Schedule

15 min 500 LBs — Coal
Print 2 heat 2 contact 5 1000 Lbs

Double Transfer is slightly softer than 69 - + has less Run out but there is not a very great difference + If we had a good blank + got rid RO think the difference would be quite small —

Must get smooth surface + Even blanks to equal the Reg Dow Transfer —

#87

Dallys plates

45cc 632 Lot 1574
2½ baking. 240 Fahr

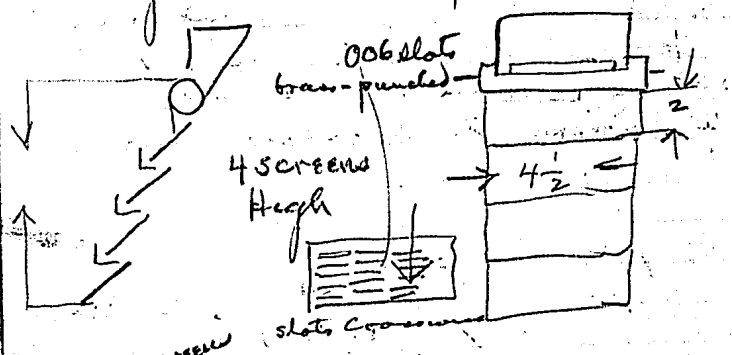
Put plates in warm Covered truck after flaming & cooled by blower the alcohol vapors out
Did it in one hour —
30 scraper 3.7 + 1200 lbs — 55 Shrinkage
3 hard releases — P.

1 OK black want fill
2 NG big piece split off — tears —
3 OK black unfil
4 NG 2 bends + Cracked at Edge
5 OK Red spots.
6 OK "

The fact that hard releases on this + tears + not welding good is due to too short baking —

No Print —

Dallyo slat screen Exports



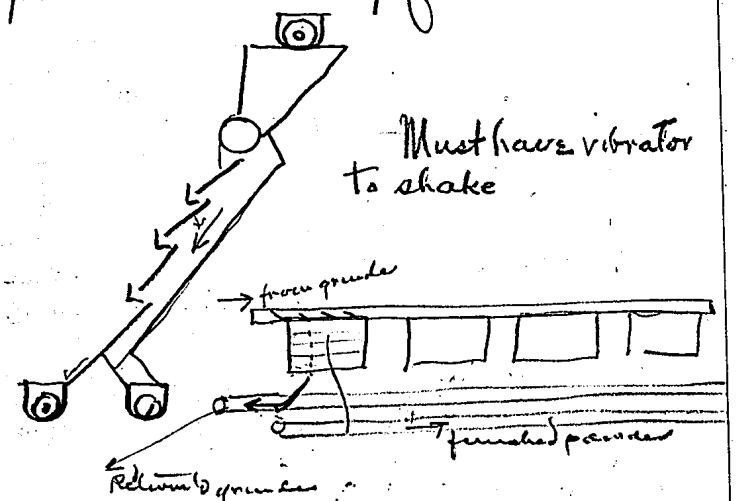
passes over screen 100 grams per minute.
of 700 Lbs in 20 hours over a screen
One foot wide = 4 passes - or using
16 screens a one pass

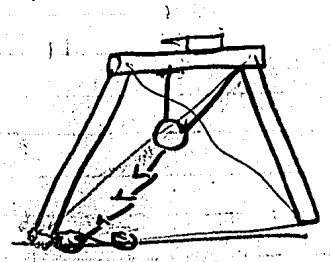
Tested 50 grms 719 records.
1st pass | 20.5 grms went thru 12½ grms of which passed 200 mesh screen
2nd pass 8.2 grms went thru 4.8 thru 200
3rd pass 3.3 " 1.6 "
4th pass 2.3 " 1.1 "

It is probable that only the stuff that went thru on 1st pass is what we want,

This gives 60 grms per pass per foot of width, per minute

60% must be regrounded =
480 lbs in 20 hours one foot wide,
for 12000 blanks requires 8000 lbs of powder - Return
4 screens Each 4 feet wide.





Dalby's final Expts Accuracy
powder —

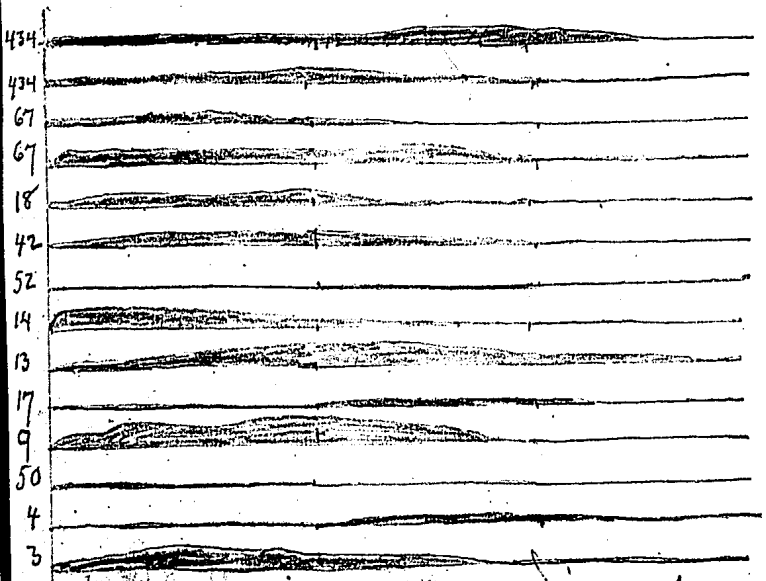
Test for Run out only



Full height of line is a thousand

Test of Dunmaddies grafited tracked White Marker by Chantrell unbeg Cam Machine — twice over, Silk wheel Velvet pad, 4 minutes —
1122-150- G3
Celluloid print, just on limit of Edwards hearing for general surface, a good many small snaps which probably Comes from Celluloid —
Surfaces on Celluloid OK - Harsh right inside Cabinet Best 2 over Ireland bearing snaps — which there must be over 100 breakones

1122-151- No G2 — On celluloid at 1st Cant hear general surface horn right in funnel 1/3 across hear it very faintly right on my limit - Very few snaps in this Compared To G3 = but there are 3 big snaps or 5 other weak snaps

G3 in condensite 719 –
Has a blank RO. general surface Velvet and is good, to me its 4 times louder than Celluloid – to Dimwiddie Masters its very little louder Geeeeee they cannot gauge volume – less snaps than in Celluloid —
2nd G3 print weak Run Outs VV surface about same as 1st Velvet, in regular precision test would be marked V good.

3rd Print G3 Condensite Bad blanks RO – surface about same – bad snaps near start, RO all way across –

G2 Condensite –
VVV RO changing at def points – Surface perhaps not so good as G3 but duller, Surface would be rated Velvet & good — Same snaps as in Celluloid

2nd Print – V run outs 1/2 way then VVVV — surface about same as 1st print, Same Snaps as in Celluloid

3rd print, Snaps same — 1st 1/3 – VVV RO — surface good Velvet.

This looks as if the grafted White Master & plating with Copper ink bath – is OK —

[ITEMS(S) FOUND IN BOOK]

Notebook Series -- Notebooks by Edison
Notebook, N-13-12-08.2

This notebook was used during the period December 1913-May 1914. The entries, which are by Edison and Sherwood T. (Sam) Moore, pertain primarily to the molding, transfer, and printing processes involved in disc record manufacture and to the construction of record blanks. The entries at the beginning of the book describe experimental transfers and indicate the effect of polishing the molds used to print the records. Additional entries relate to the surface qualities and treatment of the master records onto which recordings were made, forming the base for subsequent molds. Another group of notes describes experiments with bumps or "tits" on record blanks to determine if and how the surface might become smooth when heated. The entries in the remainder of the book describe a sequence of experiments, numbered from 12 through 369, which involved pressing powder in blank molds with a pure rubber plunger "to get even pressure all over" during the formation of record blanks. The goals were to smooth off the surplus stock (using various scrapers) after the rubber pressure without disturbing the pressed powder and to prevent the powder from sticking to the rubber. The entries for experiments 12 through 44 are by Edison. Among the results noted are the thickness of the blanks, transfers, and prints, as well as the quality of the transfers and prints. The results of the remaining experiments, recorded by Moore, appear in tabular form. The notes indicate that H. Grimes also assisted Edison. Inserted into the book is a note to employee F. C. Pullin regarding an old dynamo belonging to Edison. In addition, there are seven pages of typewritten comments, which were prepared by former employee William A. Hayes during the late 1940s or early 1950s for Vice Admiral Harold G. Bowen, executive director of the Thomas A. Edison Foundation, and Norman R. Speiden and Harold S. Anderson, curators of the Edison laboratory. The front cover is labeled "8 December 1913," "Mr Moore," and "Experiment on Blank." The book contains 135 numbered pages.

Mr. Moore:

Experiment on Blank

8 December, 1913.

[ITEMS(S) FOUND IN BOOK]

This note book contains the recording of Mr. Thomas Edison while making experiments on the development of the original Edison disc record. It is in two parts; that dealing with the manufacture of the "blank" and that dealing with the blank surfacing on which the record was printed.

Mr. Moore, whose name is on the cover of the book was Sam Moore of Mr. Edison's "Insomnia Squad", a picture of which appears in the "Boy's Life of Edison", by Mr. Meadowcroft.

Explanatory Notes

The record, "blank" was molded from a powder whose composition was wood flower, chalk, lampblack and rosin.

The powder was made by dry mixing the woodflower, chalk and lampblack to which a wood alcohol solution of rosin was added. After further mixing this coarse mixture was vacuum dried to recover the alcohol. The coarse dry powder was then passed thru a ball mill which reduced it to a very fine dark grey flour. The flour was then ready to mold under steam heat and hydraulic pressure to form the blank which had a variable thickness of approximately one fourth inch. It was soft enough to scratch and during the printing process, which was done under higher pressure, was rendered to a thickness of approximately one-fifth inch.

The blank was surfaced with a varnish which in these experiments was first applied to a metal dish and dried. The blank was then sandwiched between two of these and heat and pressure applied. The varnish sheet in this manner was "transferred" to the blank as a veneer.

"Later the process was revised with the liquid varnish being applied directly to the blank. However, this was later than the time of these experiments.)

[ITEMS(S) FOUND IN BOOK]

The Equipment

The mixing was done in what appeared to be a bread dough mixers. They were horizontal metal containers with a horizontal spiral mixing blades driven by electric motors.

The vacumn dryers were large metal ovens, cylindrical, with a swinging door on each end and with steamheated shelves. The wet powder was placed in two-inch depth sheet steel trays which were slid onto the shelves for vacumn drying.

The molding powder was placed by hand into the demountable mold which consisted of ring bottoms with center pin-hole and pin. For loading with loose powder an additional ring was employed to retain sufficient powder.

After filling the mold by hand and striking the powder off level with retainer ring, it was placed in the first press. This was a fast ram which operated upward by air pressure against a thick rubber pad. This operation expressed much of the air from the loose powder. The retainer ring was then removed and the compressed powder struck off level with the top of the mold. A thin retainer ring and the top were then placed on the mold and the powder was ready to be formed into the blank.

The molding was done in a press consisting of an upward moving hydraulic ram with a tier of steam-heated plattens. The press mold held 12 molds.

The molding operation cycle was to first steamheat the molds, apply the pressure, chill the plattens with cold water, remove the pressure and remove the molds with the molded blanks.

After removing the blanks they were ready for the surfacing process.

Page 1. Experiment (719 Blot of Powder.)

This batch of powder was put in the dryer for the noted time and then molded into blanks under 1,000 lbs. per square inch pressure while heated by steam at 10 lbs. per square inch.

The blanks were then veneered with condensite varnish by the transfer method, using a pressure of 800 lbs. per square inch, heated with steam at 80 lbs. per square inch. This was the veneered blank ready to be printed between record molds.

The other factors in the blank processing are not recorded.

X R.O. is the abbreviation for "Run Out". It means that the music "runs out", or fades out, due to areas of light printing. X

Page II. The "Rotating disc" probably consisted of radial blades used in striking of surplus power from the mold. This type of striko-off equipment later became standard.

[ITEMS(S) FOUND IN BOOK]

Page 3: "Tapping" probably refers to the method of tapping the loose powder filled mold to consolidate the same before striking it off. This consolidating method was later abandoned for the air ram method.

"Pull Out" means that when the printing mold was separated a portion of the surface stuck to the mold and was "pulled out" from the finished record.

Page VI. "Blasts" means that the fidelity of the music was lost due to the skidding of the needle in the music groove. This was probably due to the speaker not being able to record loud music at that record speed.

To polish was to run the record under a rotary brush. This would reduce the blast as it would reduce the printing depth.

Page VII. "Knocks", "crackles" and "Scratched" and "Rough Surface", due usually to defective surfaced blank. "Run outs" and "Bad prints" usually due to blanks having low density areas.

"Cracked" - Records in process sometimes developed cracks radiating from center hole due to central circumferential stresses produced by radial flow of the record under high pressure.

Records sometimes developed circumferential cracks, near the edge. These areas later designated as "Parallel cracks" - (parallel to edge). These were due also to the radial flow of the record under pressure.

The writer determined (quite by accident in 1922) that these were caused primarilu by too high moisture in the powder which adversely affected the molding characteristics.

Page XII. The test recorded on this page does not determine whether defects arose from the printing mold or the surfaced blank. Last line reads "Rouge" (i.e. rouge polishing powder) " and I think kerosene."

[ITEMS(S) FOUND IN BOOK]

Page XIII. These are diagrams of the music groves as noted radially across the record. A "knock" is a surface defect which, if it extends across several grooves, causes the knock to repeat.

"Buckles" were wrinkles in the surface caused probably by flow of varnish under heat and pressure.

Pages XIV - XVIII. Nature of this test not understood by writer.

Page XX. Edison apparently concludes that defects in records may arise from dirt particles on printing mold and on blank. Washing mold corrects the former.

Page XXII. "Surface Velvet" good" - means absence of noise arising from scratchy surface characteristic.

Page XXIII. Blanks surfaced with celluloid instead of those preceeding which are presumed to be finished with condensite.

Page 32. "Tits on Blank" are presumed to be particles of blank varnish material extending above the surface. With sufficient heat this would soften and mold into varnish surface. With insufficient - they would cause defect in record.

"Top not in Contact with next Plate". This means that the press-rams was not operated to raise the mold to make contact with the platen above.

This test was to determine if heat alone would cause the tits to mold into the blank.

Page 33. Concludes from tests that sufficient heat reduces the hazard of printing mold defects caused by tits on blank.

Difference in mold temperatures could have arisen from location in the press or the length of time in the press. This is the thought behind Mr. Edison: "Inquire how they were taken out."

[ITEMS(S) FOUND IN BOOK]

Page 34. The "Labels" mentioned here and on previous pages were impressed in the varnish. Later, because of the high rate of defective label printing, paper labels were substituted.

Page 38. "2 Heat - 3 Contact". This is the operation schedule; heat platens 2 minutes then raise ram until contact is made with platten above where it was held for 3 additional minutes.

Page 39. Note last two lines: "Would be O.K. were it not that blanks are irregular". This indicates that the blank production method was unsatisfactory. The method used is not disclosed in this note book.

Page 41. This is the test that tried out the blank production method finally adopted.

The diagram shows the mold ring, bottom and top ring. The top steel plate and rubber pad were attached to the head of the vertically operated air ram.

Page 42. This device was tested to remove the surplus powder shown in diagram Page 41.

Page 43. This page may be clarified as follows: The thought of this experiment is to find a good way to smooth off the surplus powder after it has been compressed by the rubber pad during the ram operation and (2) to find method to prevent powder sticking to the pad at the end of the operation and (3) to get it to operate commercially and cheap.

Page 44. This shows the coordinates of a blank with marginal thickness in thousandths of an inch, as measured by micrometer callipers.

[ITEMS(S) FOUND IN BOOK]

Page 49. The fixed rotary scraper was adopted for production with the loaded mold conveyed to it on a rotating table.

Page 50. The irregular areas shown on blank diagram were areas which did not print satisfactorily. They will appear on many pages which follow. The cause was an uneven distribution of material; blank and veneer. Often areas are noted as discollorations - red especially.

The uneven distribution of material in the blank was usually caused by what were known as "Tear outs". Apparently they were not noted in these tests, altho they appear to have been present.

"Tear Outs" were areas where the scraper tore out powder below the level of the ring. When molded these produced soft spots which were unnoticeable to the eye, but which would cause Run Outs on printing. The primary cause was too rapid release of the air ram which blistered the powder in the mold prior to its being scraped.

Page 52. This is the first of blanks completed as records.

Page 53. In this case the rubber pad used in connection with the air ram was not cemented to the ram head. It was placed on and removed from the mold before and after that operation.

Page 54. First paragraph indicates the scraper had insufficient length to remove all the surplus material from the mold. Second paragraph is not intelligable.

Page 56. Start of tests using 779 varnish. Character of varnish not recorded.

Page 65. Start of tests on Lot 632 varnish. Character of varnish not recorded.

[ITEMS(S) FOUND IN BOOK]

Page 68. "It pulled up surface near edge womewhat badly". This is first indication of uneven distribution material in blank due to faulty operation at this point. Its significance seems to have escaped notice.

Page 70. - Note same, "only 2 or 3 slight raises"

Page 786 - Start of series of tests on 12 blanks (#32 - #44) from blanks thru printing.

Page 110 - Summary of same.

Page 112 - Tests on loading powder into mold by means of a straight scraper. This operation was done by hand. This was the later production method.

Page 113. Tests on processing powder in mold ready for going to presses.

Pages 116 - 125. Record of test blanks 45 - 369 thru transfer and printing.

Notebook Series -- Notebooks by Edison
Notebook, N-19-04-20.1

This undated notebook was probably used by Edison during the period 1913-1914; several of the entries were annotated in June 1926. All of the entries and notations are by Edison and pertain to the construction, electrical capacity, and efficiency of his alkaline storage batteries. Most of the entries contain data and observations, probably transcribed from earlier notebooks, regarding numbered cells made with experimental iron "pockets" or negative electrodes. Also included are notes, probably transcribed from earlier notebooks, pertaining to experiments made with various electrolyte solutions and positive electrode "tubes" and to tests made under different charge and discharge conditions. Among the earlier notebooks consulted are N-06-09-05, N-10-02-24, and N-10-10-31. The notations from 1926 consist of brief observations about specific data, along with disparaging remarks about former employee Dr. Otto Grothe. The front cover is labeled "Very Important." The pages are unnumbered. Approximately 50 pages have been used.

Iron mix-various.

80.5	114	225	33.5
		*	

*

40 + 50 about the same, but after 75 amp 50 rate goes above —

at	100	to	105
	125	"	110
	150		114
	175		116.5
	200		118
	225		120

If we charge a E18 at
30 amp then at end 225 amp it will be 12° above atmos
40 " 17.5° "
50 " 23.7 "

It is very desirable to charge at low rate for heat reasons —

E 18. Cell discha 30 amp rate
it was chgd 8 hours 30 amp.
Stood over night to cool to normal

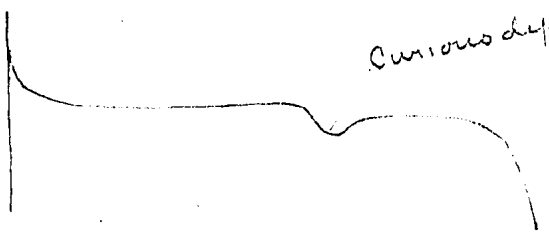
Air Temp	Cell Temp	Amp	Dif
72.5	71	0	= 1.5
71.5	74.5	25	+ 3
73	78	50	5
73.5	83	75	9.5
75	86.5	100	11.5
76.5	90	125	13.5

above cell only gave 124 amp to 1 V

F

Fe = 534 A-
Discharged at 300 ma after long charge

Normal Temp discharge	110° discha	121°	135°
1350	2575	3000	2575



Extra capacity is below 1.15 Volts

Cell No 597 Short chg

If charged normal + discharged at 135° it gives a higher capacity, + 3/100 higher voltage, than if charged + discha'd normal.

If charged at 135° + discha'd normal. capacity is only 65% of the charged normal. Voltage is less than 1.18 average against 1.27 See next page

Iron Alum, enormous quantities used in dyeing

$Fe'''(NH_4)(SO_4)_2 \cdot 12H_2O$

Colorless crystals, crystallizes readily

It is ammonia ferric sulphate

This on ignition should give very porous iron, having 12 waters

Ferrous Alum only 6 waters,

Yellowish sediment on the hard rubber of cells is a very basic iron sulphate,

Long charge

The discharging voltages in this cases are about the same

But the cell charged hot has 5% less capacity than chg + dischg normal + chg + dischg + etc.

The long charge acts entirely different from short charge. Why?

Experiments with C.P. Nickel strips, and regular irons, with, and without Lithia in the KOH.

6457	21%	2 grms LiOH each cell
6458	"	3 "
6459	"	Saturated "
6460	"	1 gram "
6461	33%	alone
6462	21%	Alone

24 hours charged - all nickel strips slightly tinted

24 hours Reversed — strip had on

6457	0.0069	7/8	second charge 33% has quite a deposit of X on all others had deposits but not so much
6458	0.0078	7/8	
6459	0.0135	7/8	
6460	0.0092	7/8	
6461	0.0200	7/8	1 grm Lithia is next to 33%. 58+57 quite small
6462	0 0080		

21% only a little as 6459 is equivalent in ions to 33% nearly it tends to shows Lithia helps to diminish X deposit.

over

Note, Brightness may be due to Mercury

6459
6461
6462 } is attacked very slowly by dilute HCl. Kept at nearly boiling heat as 6462 Clears up in the acid it resembles in appearance exactly 6459 when first taken out so all the deposits (10) 6459 6461 6462 are the same-
It certainly looks as if the deposits were partially amalgamated, This would account for the brightness of the strips + in the case of 6461 + 6462 the deposit was not sufficiently supplied with Mercury to make them bright
Another thing is slow action in HCl which may be explained by Mercury. It looks as if Lithia favors amalgamation of Nickel surfaces in Alkali + thus give loose deposits of deleterious material + loosens old deposits = 6459 after ½ hour nearly boiling is now bright, frost by rubbing slightly with finger its silver like showing that it is amalgamated hence Lithia Conduces to amalgamation + holds the Mercury in the iron + also evidently removes some scum that is not removed by KOH alone otherwise Nickel strip wouldn't amalgamate →

2nd Reverse

6457 — Very bright no gas on H Cl. grease on as H, of film clean
6458 "
6459 Brightest deposit grey. shows smaller crystals
6460 Very slight brownish deposit, not all over clear in 2 see in HCl
6461 Black heavy deposit,
6462 " " not so much as 6461

After 1 hour in acid 6461-2 still had dull grey deposit, had to polish off with rag which got black from 6461 which has more deposit on of this grey than 6462 although it looked brighter
Scarcely a sign of amalgamation, no Hg under microscope.
So far the results would indicate
1st Lithia keeps Hg on iron + prevents migration on reverse, hence iron do not go into solution on dischg + permit deposit of oxide inside Tube possibly Hg holds Co + other metals back in iron

OVER

2nd Should cell get reversed, very little Fe goes over & considerable Hg which wants to follow the Fe Any scum or film X stuff forming on Nickel tube is loosened up by tendency of Lithia to cause anodic dissolution Without Lithia Considerable iron migration & scarcely any Hg. which is the reverse when Lithia used.

Remarked that I thought Nickel was of Soluable in KOH Containing Lithia

2nd Reverse 40 hours Ni strip as cathode

6457	.0078 Fe
6458	.0037
6459	.0075
6460	.0080
no Li 6461	0360
6462	0105

Nickel strip Anode 80 hours

6457	Pink Tint Very light
6458	" in spots
6459	" "
6460	" Very light
no Li 6461	" "
6462	Blood red, deep like red Lacquer

All the colors came off instantly on dipping in water containing H_2O_2 Water appeared a little pinkish Dr G says only Trace Mn but think his test NG

3rd Chge Ni strip Cathode,

6457, 6458, 6459, 6460 } Bright, Hg precipitated

6461, 6462 } dark coating

6461 thickest coat all but 61+62 clear up bright after air oxidation, 61+62 dont clear in 5 mins All the iron grids purple When Ni strips taken out H_2O runs off as if greasy. Purple is Either Mn or Rubber Compound

Appearance of a lot of little test cells

5775 } Fe gray = Tubs light yellow brown no crystals
5776 } Fe gray – Tube Lighter color – has crystals
5777 } tint of yellow on sawed portion of rubber
Same as 5775 – tubs yellow, crystal on inside part

5778

There are 6 or 8 pages in a general note book describing condition of tubes & grids of test cells (small) too long to Copy –

Wayte rubber holding Fe or Ni a bottom is coated with mercury = Micro shows fine globules & states that it is certain there is a high resistance short circuit in many of the cells – Also many have fine Crystals on tubes & other parts – Crystals disappear when Elements put in Water.

Equivalent Ions

21	10.9
23	10.9
25	11.9
27	10.1
	10.81

Short charge A cell 597-
Charged normal discharged 135° fahr
gives higher capacity & 3/100 higher
Volts than if charged and discharged normal

If charged at 135° fahr and discharged normal
capacity is only 65% if charged normal
& voltage instead of 1.27 is down to 1.18

Long charge

Discharge voltage in this case is about
the same. But cells charged hot has
5% less capacity, than when charged
and discharged normal. and charged &
discharged hot
The long charge acts entirely different
from the short charge.
WHY ??

Rzq Tubes Bi LiOH group.

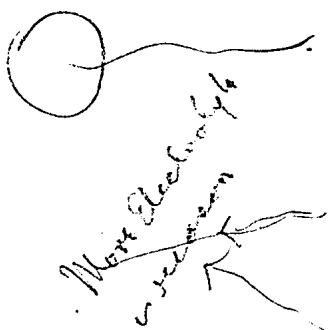
Charged cold discharged Hot
Capacity + Volts good 1280 ma.

Charged Hot, discharged cold 500 MA

Charged Hot discharged Hot 900 ma

Evidently charging hot bad for Bi

Some Bi cells are fair when chgd +
discharged Hot. 1200 on a 1350 MA Tube



I say Fe is not affected like the Nickel in charging Hot

Plain nickel in 21% KOH alone, gives 1/3 of its capacity, on charging Hot 130 fahr gives 1/2 capacity when KOH has the 2 grms LiOH in it

With 21% KOH 2 LiOH. Bismuth gives 3/4 of capacity

Regeneration of bad irons from a big Cell. using one Fe pocket with 4 Ni Tubes in small can, Tried 10 cells. I say that the irons dont really go bad, Think it goes passive from want of use

The average of the 10 irons when we

Started was	896
8th run	2289
15 "	2540
16 " after full charge and shortcircuited 3 times was	3047

Evidently most irons can be brought back to capacity by fully charging and short circuiting, and repeating this several times! —

Iron in pockets gives different capacities if pockets plated with different metals, Antimony seems to be the best. A tube with Fe + flake Ni was no good, it may be nickel acts Catalytically + kills iron,

3057 #69 Dr Grothe
3058

60% Fe
40% Cadmium } 5 grams

Irons when run in cold temp, bad, no matter how much the weight of the tamp is increased. 2½ lbs or 4.88 lbs.

Think solvent action of the Hg Causes Fe To get more dense & Shrinks away from contacts Look like meld the dense iron under micro,

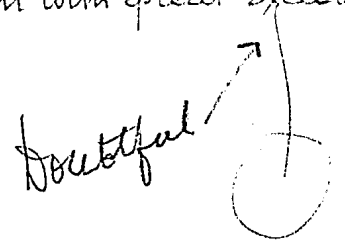
Hypophosphites of Soda seem to heat irons -

Reg Fe wt 3 grms heated to 212 for hr lost 3/10 of 1% — This sample exposed to air & saturated with moisture absorbed as follows

15 Min	6 Milgms
30	8
45	9
75	11
105	14
135	14
225	14
315	17

It appears that we cannot use Iron as a negative of Bismuth as it is to be used in Ni Tubes, perhaps Cadmium or Cobalt may do, -

It is probable that in big cell Nic Fe loses capacity as fast as Ni increases & we get no gain like we do in little cell with great excess of Fe.



Shows how Bad our little tube test is —

This belongs to Nickel Boat

Notebook Series -- Notebooks by Edison
Notebook, N-14-01-01.1

This notebook was used by Edison, probably during the period January-August 1914, and was annotated by him on several subsequent occasions, including January 1, 1916. It consists primarily of notes from the numbered battery record books (*Thomas A. Edison Papers: A Selective Microfilm Edition, Part IV*, Notebooks by Edison and Other Experimenters—Battery Record Books) and other earlier notebooks pertaining to alkaline storage batteries. Included are data and observations regarding the capacity and efficiency of numbered experimental cells. Many of the entries relate to the composition, construction, and treatment of positive electrode "tubes" made with nickel and other metallic flake (including cobalt and bismuth flake) or treated with other metallic additives. Other entries pertain to negative electrode "pockets" made with different preparations of iron, to the use of different electrolyte solutions, and to the possible rejuvenation or "regeneration" of used battery components. Inserted into the book are several loose pages of notes, including a 1910 memorandum from Walter E. Holland to Edison regarding the construction of three experimental cells. The front cover is labeled "Very Important." The pages are unnumbered. Approximately 130 pages have been used.

Arsenate of Hg is sol in KOH

I think Arsenic metal is reduced to Metallic if so is there local action, or what—

Cant Formate K formed in our cell in presence of CO_2

Hurts Know – all cyanide Compounds hurt iron, ...
Why – Ferrocy Fe decomposed by KOH.
Is it Shuttle Ox & Red

Notes Old Green – 1907

Iodides in electrolyte very bad for Nickel reduces capacity more than half.

Arsenic Acid is bad for Cell. Arsenate or Arsenite, diminishes Capacity 20 @ 25% 100th run in small test cell—

Formate K is bad, reduces capacity 20 @ 25% 100 Runs.

1907

3 | 25' / 54

1907 says this shows charging rate is bad, and Cobalt flake is much worse than Ni flake.

Iron is not active at low temps. requires like Carbon a certain heat when in a certain physical state to make it reeact rapidly. Only way out is to get more porous + finely divided irons + keep down Hg or abandon it, + increase discharg rate for heavy work by increased surface —

A 5 gram Iron pocket giving 1480 to a volt
Charged + dischgd Normal, 15 hours 400 Dischg 300
Same 7z charged + dischgd hot 110 Fahr
gave 2550 To a Volt, Why?

We never gave Caesium or Rubidium hydrate a good test.

Ni Tubes never plated always went bad on hot test, - See further on claiming this

Ni tubes run in saturated LiOH get a very red coating on tubes cant be rubbed off. Ogna Regia takes it off an quick in transparent sheets having a reddish stain After 50 runs irons + grids bright, alloy yellow different from Reg tubes, This is on discharge, but after 100 runs a Brown red strongly adherent to tubes This is 6059. Electrolyte being 21% KOH Saturated with LiOH.
6059 is put in test tube with 100 cc water + 100 mlg HCl for several hours over asbestos

possibly gelatinous Ferric colloid

on hot plate, in few minutes clinging red wipes off, dont think it dissolves but HCl dissolved off something that made it loose

Aluminum is bad in KOH NaOH, Worst of all,

3 grams of ferrous hydroxide put into Elektrolyte 21 KOH 2 LiOH 150 Runs actually increased the Capacity a little,

Why ?

→ Acetone is bad

NaBr seems to help Irons
300 Mlg Bromstone in Electrolyte 21K 2Li seems to increase capacity of the Irons
Can it correct passivity ?

Nitrates are bad either for Iron or Ni

Carbonates K dont hurt I even seems to help - when KOH, but hurts in NaOH. when it Na Carbonate, 15% NaOH 2Li

Hydroxides like Fe + heavy plates Index

Reg cells, 5 time normal boosts 6 months dont hurt in normal Electrolyte but hurts bad when weak ? why Extra heat possibly

Must Expand greatly in length.

We should Precip Ni by LiOH+ace
if Li is washed free or is there a Combination

Perhaps the gas which comes off on
putting in acid is air in the pores

2% Water

Many count
26.9 KOH

A saturated Solution of LiOH in
water causes Tube to be Twisted
Cork Screw like and bent.
$Ni(OH)_2$ must be an acid & Li forms a salt
with it hence enormous swelling
June 1907

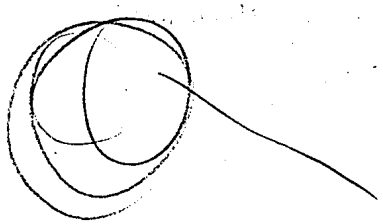
$Ni(OH)_2$ absorbs water from the air
There is always some NaOH left in it
also Carbonated

Took 10 grms green from drum
Threw 20 times in - put on Watch
glass, in two hours on hot plate
on a piece of paper Lost 85 Milg
in air Gold regained 191 Milg

Ni flake thru hydrogen is no good
must be elastic + not dead to make
Contact with Walls of Tube

5 grams Lithium Chl 21 KOH better
than 21 K 2 LiOH.

Bismuth is not good. except with LiOH.
only gives mg +



This seems to show porosity is not Enough as Ni does not get enough ions to give capacity

Phosphate Lithia is insol as KOH.

Evidently Li displaces Ba in the Electrolyte

Another Case where Phosphoric Compounds are bad.

Phos bad

& Carbonates with Ni Oxide from KOH

There are Cases where Phosphorus does no harm

Green soaked in Titanium Sol 21K OK
" Zirconium " " OK
" Nitrate Didymium " OK
when LiOH put in it reduced capacity
Green soaked in 4% Bichr. increased " slightly another piece further on says Bad,

Pure Ni Tubes. Ni rings Ni wire -

100 Runs 1160, 1140, 1147 } 21% 1263, 1263, 1260 } 21 2 LiOH.

1360, 1353, 1353 } 25 2 LiOH. 1433, 1433, 1433 } 27 3 LiOH.

End Book No 4

Book 5 Soaked Green in Orthoplas LiOH precip by

Potash then in Chl Ba — without LiOH gave 987 with LiOH 2 470 —

Soaked KSO4 then Sr Cl — gave 1219 + with 2 LiOH. 1240 —

Antimoniate K + Ba Cl. 843 — with LiOH 1042
Conc Stannate Soda + Ba Cl. 1214 with LiOH. 1258

Nickel may be a compound
Yes here is a method of separating
the two, or something in $Ni(OH)_2$
Used Combines with LiOH,

It is remarked here that acid treatment of flake removes Al_2O_3 & Fe,
Rzg Ni along here with 2 LiOH. was giving
1330 often 25 hot runs
. End book 5 #8000 group

Book 6 = #7450 group

Sr Carbonate precip in pores 300 Rum 1133 - with LiOH 150 Rum 965
Ba Carbonate " 300 Rum 1080 " 150 R. 1038
Boiling green in Conc $HgCl_2$ washing acet free show sponge loss capacity after 150 Rums
Especially when LiOH is used —
Without LiOH lost 70 in ah 150 rum
with LiOH lost 250 — another Dup —
Without LiOH, Lost 159 — with LiOH, 267 —
This is strange —
Alcohol saturated with $HgCl_2$, + then washed free much poorer capacity when LiOH used —

Soaked green in Conc $Ni(OH)_2$ in Ammonia + NH_4Cl. boiled with KOH, washed well.
150 Rum no loss capacity. It was Cut out 1150 —

No def when strontia used

KOH decomposes Chromium as known to make Irons good

Possibly closed pores so not enough ions to react,

Another Case where phos combines to dead the Lithia in KOH. We shall have to test for a while for phosphate —

Bismuth — 10 min soak 1/2 strength Conc $BiCl_3$ Nitrate left all night 10% KOH. Then boiled + washed free of Cl. 6.41 wt —

Cold	50	150	200	
1033	1120	1120	1077	Co
1155°	1450	1239	1176 —	Iron 1290 — Li Off in this

Another with Bi made nearly same went to 1367 on 100 + then bad —
Another where tubes soaked went from 1130 to 1380 on 100 + then went bad - 990 —

(green soaked BaCl KSCN — No LiOH, better than with LiOH —

Soaked BaCl + Chromate K — Irons go bad —

Soaked Green in KMnO + BaCl, only gave 580@640 - Cold — bad —

Orthophos K + BaCl — no Li 50 Run 990 but with LiOH 467 — Note bad effect of phosph on LiOH.

We were Oxdzg flake at this time —

Evidently Li dont Combine or displace CO_2 from Lime,

not oxidzd now —
Another Case cobalt phos in green effected the LiOH a it went bad

8731 group RA 1072 at end 200 Runs 200 higher than the Dup in LiOH —

When mg CO_3 a others are precip in pores of green The LiOH dups are much worse than Reg 21 KOH, with phos lime Capacity about same K7 a Ca(OH)$_2$ same capacity

Green soaked in Conc $BiCl_3$ in Acetone LiOH — which seems necessary for Bi

350	450			
1615	1550	remarked 1164 too heavy		

Book 14

Exposing green for 2 weeks did no harm —

~~out the loading~~

Connected 2 gram Tri to Each Tube —
ditto 2 gram B 2 Tri
ditto " Pb & 2 B.
ditto " arsenic only
Did neither good or Bad

Cd tube

Tube filled with 1/8" of each end, the ends filled and 5 ohm went bad only 967 milliamp heavy — flake & green gat Chance to expand & get at contact.

Guess loading wt changes & its liable burst tube from water lubricating & making dense & too much load wt —

Dried Alumina seems to do not harm but undried precipitated Aluminum precipitated in Electrolyte is very Bad —

This seems true for Silica —

Drying Changes both or makes them inert, non colloids

probably true of Zr & Ar & Ti its only when not dried they are bad,

Because dried

Silica precip in green 2/10 lt. / did no harm Even 1% no harm Neither ded 1% Alumina but green it decolored out, or dried

1/2% Co precip in green showed improvement, 1% decided improvement, 350 mm 1410 –

2 grams Silicon connected Each Tube Went bad only 480

Bi & Si dello. —

Cr 2 gms went a little bad

Vanadium is Bad for cells

Neither Zr or Arsenic precip in green in small quantity is bad — or Ti

1164 green is heavy green —
Mixed 20% Carbydrous B. with it

Cold	50	100	150	250
1260	1530	1720	1747	1555 Co -

Burnt 3 places —

30% B. Oxide only dident do as well
50% " " Much worse

Another 20% B.O only 500 Rum 1415
it showed with a 30% B.O only
1887 to 1/2 Volt after 200 Rum
but only 1267 to .9 - 72 Good 9
guess

Effect of decreasing Metallic Aluminum

	100 Rum
4 Milgm -	1230
3 "	1230
9 "	1232
2 "	1125
8/1 "	1062

20 Mlg - 175 cc
21 p Heat 2 hr -
appears OK

This apparently Bi_2O_3 does not conduct as $Ni(OH)_2$ alone without flake gives 200 Matt—
What does it do

Green mixed with 16.8 Bi put in tube without flake
50th Run 103 Matt

2 grms Tellurium Connected Each tube, not good—

ditto 7% Va alloy—Very bad 610

734 green 16.8 Bi — 1st 2 charges in 8% LiOH, 1/4 rate. Then changed to 21K 2Li—

500 Run	800 run	1050 run
1487	1524	1577
1250	1300	Bad Cont.
1423	1333	

Another one charged 4 days loose in 4% LiOH/rack then put in 21K 2Li grms about the same

5.145 / 7600 - / 1477 — 1477

5.145 mg ℓ Mach

2 lb cowright lamp	1477		1073	5521
2½		5.351	1103	5902
3			1050	6027
4	1347	5.641	1123	6333
4½		5.510	1157	6399
5		5.390	1193	6.445

2 lb cowright lamp Copenhagen flat grain

End book 15

filing down burrs
Making mist
Lime Carb mixed in green
unpowdered form does not
harm — used powdered
Marble

It certainly is curious, we have much to learn about the iron

Possibly Ni plating is not good see 3 pages ahead where iron plated iron gives good results.

(Perhaps Ni has some bad action on Sty. Try iron plated tube without flake - with flake without Hg (Calgon))

Celluloid dissolves in KOH.

Iron pipe nipples 10 gms only gave 2100 Mach No flake —

with flake went to 250 Mach on 200th run coherent without flake 1230 —

This is Curious

Bi dont work without KOH 100th Run

No Bi	933
1/0 Bi	1380
2/0	1533

Took piece film Celluloid folded it in tube & Loaded it

Didnt do any harm 5/1 950 Mach 1000 on 250th Run

Bi in NaOH & various LiOH not near as good as KOH,

5 gram Coke Req for complete Neut - But with

	Cold	100 Rev	Neut
5% Bi in Fe	590	45	1510
10%	1175	85	1260
15%	2130	85	1260

Note

This goes to show that Bi dissolves in KOH & is reduced by the iron, or lowers its voltage so it can't reduce the nickel but when heated its voltage is increased or the Bi is oxdized & no longer interferes

Tantalum is now known to act as a Valve like Al in rectifier & more strongly -

Tantalum Rod - 1 gram connected to tube

2 gram Aluminum Metal Connected to tube Gold 1093 - 50 Rev no Capacity at all

Thus must effect the iron

NO_3 Oxidizes Fe_2 & themselves are inactive hydrate probably?

It may be that Ni acts catalytically in both & is used both for Ni tubes & Iron tubes — Can Tongue 2 cells one Ni plating on tubes pockets & grids only the poles plated

Have got exposures Nickel goes back from Incandescence OK

It may form iodate film or Combination with $Ni(OH)_2$

Dolezalek finds what Forbes does

Has soluble Si Can act

20% Bi tubes —

2 grms K Nitrate in Cell

Very Bad 587 on 50th Rem Great gave 1623 to ½ volt,

2 grms Na Nitrate only 400 to .9 + 1683 to ½ volt, Aluminate Na hints some

Reg Ni Reg tubes Not plated

gives 1258 300 Rem 1190 500 Rem

600 rem 1073 — See note back

2 grms Iodide K —

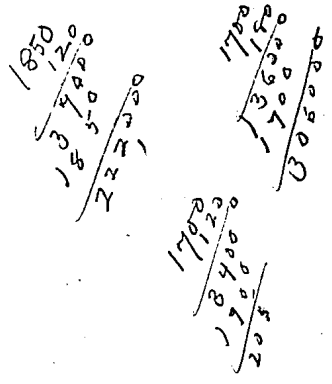
Bi tube — gives no charge or discharge

Bi tube 2 grms Na Silicate

50th 1355 100th only 120

130 to ½ & 1250 hot.

7613/150'40 (2



Should have been run longer on board

Sulphate Luna in case no harm

25% Cobalt precip in Green

Cold	50	100	150	200

Note says of this had Green run on Grand Reversal turn colored brown Green very high —

25% Cobalt.

Cold	50	150	300
1083	1490	1400	1357

500
1193 —

Arsenic probably reduced to metal

This not run as long as 4 yr old 7/2 below - but these 4 yr olds 1050 to V in many Cases

Proves $N_2(OH)_2$ dont go bad its colloids destroying Contacts

Later Aug 1 1914 Cut open 1/2 of 2 old tubes 4 yrs that gone down bad - Fried flake Contacts on test machine found that 85% of flake sections were in Contact Evidently Ni itself goes bad, Colloids or dehydration, or Combination with some acid

Arsenic bad in B1 tubes - (1e)
Arsenate Na in $Cl_2O_3/1.0$

Mix taken from old 927 + 928 tubes - tubes washed free of KOH. dried 8 to 8 358 - taken out acc flakes except perhaps 15% removed - Mix treated with weak H_2SO_4 - then washed + dried.

Book 16 - 4443 -

Cold	50	100	150	200
1380	1293	1282	1327	1383
250	300	400	500	
1385	1417	1393	1350	
550	600	750		
1327	1153	1073		

Perhaps 7/2 went bad or might have run longer

Hydrofluosilicic acid precipitates Potassium as potassium Silicofluoride
Insol. — Perchloric acid precips K

Acid Metaantimonate of Potassium gives white precip of Sodium Metaantimonate — Li, NH. + Earth metals does same thing —

There is no doubt but that when H is given off more on Change, that of the Ni & Fe plates are too close we get H_2O_2 + then we would decrease a limit to the charge of the iron perhaps thick packets by poor circulation preserves most of the Fe from reoxidizing by H_2O_2 formed — it would be interesting to put paper between plates to stop oxygen going with Fe Packet

I had a Chemist (Sic!) test for H_2O_2 but he couldn't find any —

test Electrolytes of Chgd Cell for H_2O_2

To make $Ni(OH)_2$ more porous precipitate $NiSO_4$ / Manganous SO_4 } by NaOH then wash a dry put in tube put plates in 21% KOH or NaOH & Oxidize to Manganic + wash out as Manganate K

ditto $NiSO_4$ – $CrSO_4$
" $NiSO_4$ – Stannous SO_4 –

Potassium Biniodate Insol Water – sol very dilute acids – Does it react possibly reacts Ni gd Gas

Potassium Hippurate insol cold sol Hot water,

Potassium Iso-purpurate V slightly sol water – Explodes dangerously at 210 C – H_2SO_4 Explodes it its K Picro-cyanate,

Potassium Nitraminate only sol Hot water – Explodes violently on heating

K Perbromate only slightly sol water

Ditto K Perchlorate slightly sol water

K-periodate, v slightly sol water

K perruthenate slightly sol Water

K Pertungstate slightly sol water

K Phosphite only sol Hot water

K Phtalimide only slightly sol water

K Piperate, only sol Hot water

K Pyrosulphite only slightly sol water

K Silicofluoride - only sol in Hot water

K Sozo-iodolate (K Di iodo para phenol sulphonate) slightly sol water

K Urate, V v slightly sol Water

Lithia Borate, V slightly Sol H_2O
" Fluoride " "
" phosphate Insol water

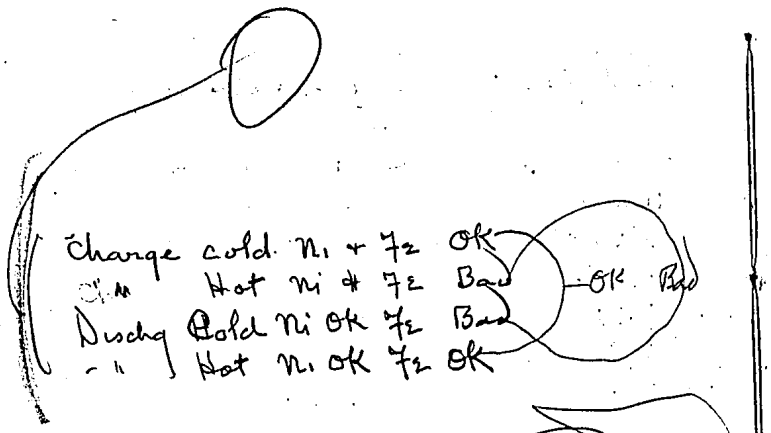
Think Fe_2O_3 from fusing anhydrous Sulfate iron in NaOH + Sulphate Soda, will give a good capacity at lower temp than Fe now ~~Nickle~~ Marked - its very fine - & possibly it will be best without Mercury as that leads to Crystalizing & make it Coarser - 1st Weber & Smith test Reg iron without Hg for effect of Cold

Cells with work KOH, Can be reduced by passing Sulphurous acid - I gave rapidly = product K_2SO_4 Try old cell thus + wash out K_2SO_4 -

Old iron from 4 yr Cells if washed with 3% Sulphurous acid - & ground thru 150 mesh is nearly as good as new, Apparently wants a reducing agent,

Strange thing is that iron looks black when taken out of SO_2 acid if washed & dried as is usually used all thru & yet runs good -

Strange!



The great problem is to equalize these two opposite Effects, because in the Cell one works against the other

We Know that Bi in NiOH, causes it to give 2½ times Reg does on hot discharge, Does oxidation of Bi give local heat enough to cause Ni OH to be easily Oxdzd while Electrolyte is cold, Cobalt would also, this may be the Explanation

Nickel tube on charging hot + disch hot gives only 1/3 the Reg temperature Charge + disch Capacity. 400 @ 50 when gives 1350 chgd + disch Normal temp — its not the iron as that gives high capacity on hot discharge.

Find from smith about Capacities
Chgd hot disch'd Cold
" Cold " Hot for Ni + Fe
Want these Curves —

We found that iron gives greatest Capacity Reduced Cold Oxidized hot

Nickel. Oxidized cold reduced Hot
is the above OK see Smith

Nickel tube chgd Cold holds its Chg in hot 130 + gives full reg Capacity. Therefore when Ni(OH)3 is formed its stable, but when Electrolyte hot its hard to Oxidize —

Is this Correct

Possibly both iron & Ni should be both on chg Cell be in cold Electrolyte & But on discharge the certain iron should have heat on its dead at 40 degs

But the Ni is also effected & Smith must find if its Oxy hot or cold that causes loss Capacity—

Its probable Ni wants to be Chgd & discharge Cold While Fe wants just the Opposite

Aug 1 1914 — Iron in new Ott #4 dia — only crimped around Edge. gives 2700 Coulombs — gives 1900 at 350 deg—

Jany 1 1914

Important to work on getting Iron finer in cell

This will increase watt efficiency - & also act at lower temperature

Have I ott make a larger batch of Iron Ox from fused Na_2SO_4 + NaOH, in which anhydrous Fe_2O_3 is dropped using slight Excess NaOH. This is practically Colloidal Iron & product could work without Heavy reduced by Hydrogen if not reduce at lowest possible temp by H ~

Jany 1st 1916

Made a lot of tests but in the End they were no improvement

9/10 of Volt —

Book 11 =

The higher the hot discharge the older is the Nickel but on board gets lower

Evidently the Nickel takes a higher Charge when hot after it gets old but at same time its Cold charge gets weaker —

Book II 2501 – Case where Fe Changed after run on board a rerun right away – losses 145 mah Capacity. as if iron poisoned it or else new iron was in peculiar Condition passing effect out fresh Hg + this from Hg scum on Nickel —

(It may be Hg is a bad thing

(As Oxidation of Hg on cathode Makes a tenacious film + an insulator

(May be Iron itself goes down after few runs test iron to it

Reg short (old tubes) soaked 6 tubes — soaked in gallon 21% KOH for a week gave not a trace of LiOH in the gallon Analysis of tubes gave 700 mlg of LiOH + 1800 mlg KOH per tube — on long tube this is 1 gram LiOH that always in tubes of keypel in 21% KOH.

Latest combine

Holland: test of big cell in water Changed from time to time showed LiOH. Kept coming out after KOH. was practically all removed He has record —

No LiOH Combs Stable in 21% KOH but decomposes in water

21% KOH saturated with LiOH. Contains in 100 cc 2.8586 Milgms LiOH.

15% NaOH saturated contains 3.2936 milgms LiOH—

K Stearate Sol 21% KOH, almost same as 21% KOH saturated with LiOH.

With the Cobalt Sulfate ~~seal~~ 3% to 35% Each 5% increase ~~output~~ life 50 Runs—

Reg 7.500 grain soaked in strong Cobalt Sol dried + pped in grain gives loading wts of 7.160— probably makes it harder + prevents heavy loading by deforming— Eventually wax at NaOH will give heavy loading by deforming a porous grain + make gas to burst that must be reason why NaOH worked so unsurprisingly well when pores filled with Ba SO4 etc—

Here is a Clue =

Heavy loading wts in many Cases give only 1040 to 1100 on 50th run

3% Cobalt SO4 up to 35% soaked in Reg grain gives 7.160 to 7.210 for every degree of strength,

Clue

Practice in working Ni Reg
Soaking in Conc Cobalt Chloride
that it was very different
to get the Chloride out many washings
& 4 days soak — Eventually pores
are very fine being filled with
$Co(OH)_2$ & thus circulation very
sluggish for Chloride —
Also this must harden grades
& gives low loading wt.

A Later Expmt shows that the
Water used to wt of Ni was
entirely too small
Mastication probably
Comes in — Using same dish
& 1/10 of the Ni got OK
with 1/5 of the washing
of the big lot.

Test of a Ni tube provided with index shows that a short tube of mat restrained the mix will expand 1/10th of an inch on charge 1/10th one third of this due to putting in 30 KOH + Li OH without Current —

Reg short tubes (old) soaked 6 tubes in a gallon of 21% KOH for a week, showed not a trace of Li OH. in the gallon —
The assay of the tubes showed over 0.700 Milgms of Lithia per tube or 1.800 Mlg KOH per tube there is about 1 grm Li OH per Reg long tube, Holland has record

Test of a Reg Cell in Water Charged from time to time Showed Li OH kept coming out after KOH was practically all removed Holland has record

Gradually some green — this shows too much flowing of gram in bed

Both Cobalt & Uranous Hydroxide Aid Ni mercury Life & Capacity — Neither and reduced by Fe as Iron will probably not be affected This is not true of Bismuth. Ag

A Ni graphite charged against a platinum strip gives 750 to Volt & 900 to .3 Volt only gives 375 @ 400 to V when placed close to an Iron Rod probably the free H from overcharge of the iron passes thro holes & reduces the NiO_2 Continuously & prevents charge fully

Note if this is true that Chg which circulates Liquid more rapid should increase this effect, Also A4 having such small Electrolyte should have big circulation, perhaps trials reqd. Wt Lose 8% as against short test tube cells & it may be troubles with Bismuth big cells

If all this is true should have a paper Sep between Ni & Fe to keep gases apart, - Can prove by Chg Ni & Fe Sep & use porous Caps then assemble & discharge

Graphite Nickel

I say if a 1200 mAH fully chgd is placed with a nickel discharged then on charging for say 200 MAH with 100 MA flowing — The Nickel will receive that amount of chg The Energy loss on Fe could be great but should be small on the Ni Now on discharge we should get nearly 200 MAH because Fe has great Cap nearly Yet we only get 100 MAH. (Figs from Fe Indicates Ni Ch?)

Ni_2O_3 40.67 % Oxygen

NiO 54.23 % "

13.56 % of Oxygen Capacity

7 grams Nickel going from Ni_2O_3 to NiO_2 should give 3000 Mah —

Old book Nos 9375 -

18 groups 3 to group of Nickel in small tubes with & without Lithia, shows on 50 Hot runs that 21K 2 Li gives average 422 on Hot

But Dups with 21K no Li only average Hot 156.

Showing great Capacity

Yet 50 Rg Capacity was with Li OH about 100 Watt hours than without —

The Li OH, Causes Cell to Take & give a greater Charge when hot, 2.7 times more

Why

Presence with Li OH 28.9 w alkaline & without only 21 w perhaps

9375 old book

Notice that deference between 50th Run Cap to V + ½ Volt there was a deference between Cap at 1 V + ½ V of only 42.8 Watt when no Li Oh was used 21K but when 21K2Li used the def was 115.6 Watt 15 groups 3 each used to get averages —

Volts 2.89 grams argument 21 Li Oh

Can it be that Lithia works on the iron instead of Nickel as always supposed

average 15 groups 3 each

The Capacity to V on 50th Run was for 21K2Li 1165

for 21K NO LiOh 1186 — S

In this case all the LiOh did was to increase the Hot capacity + ½ cap

Volts

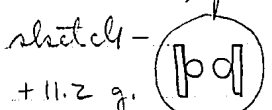
Misc. Exp. #1752-74.

Mr. Edison: You wrote me last week about trying a small cell with an Fe pocket short-circuited to a Ni tube as the positive electrode and the same for the negative electrode. I had 3 cells made of new tubes and Fes, positioned in glass jars like sketch — filled these with 21 of 10 KOH + 11.2 g. LiOH per l. and ran as regular tube cells with following results:



RUN	CELL A 1V	CELL A .5V	CELL B 1V	CELL B .5V	CELL C 1V	CELL C .5V	AVERAGE 1V	AVERAGE .5V	
1	963	1147	963	1147	983	1160	970		
2	1147	1317	1133	1310	1127	1293	1136		
3	1160	1310	1150	1317	1167	1300	1159	1309	
4	917	1033	843	967	920	1033	893	1011	— Monday run.
5	1110	1277	1110	1277	1110	1237	1110	1264	
6	1120	1290	1117	1283	1097	1233	1111	1269	

Voltage averaged 1.116 on these tests.

The volt curve did not drop straight down from 1V to .5V but had a tail, showing, I think, that the Fe gave out first because it did not get fully charged. The tube which is in front of the Fe would naturally shunt some of the charging current.

Will now try these for holding their charge and then will reverse the polarity and see what happens.

W. E.

Notebook Series -- Notebooks by Edison
Notebook, N-14-01-01.2

This notebook was used by Edison during the periods January-March 1914 and October 1916, partly at his West Orange laboratory and partly at his winter home in Fort Myers, Florida. The entries from 1914 pertain primarily to sound recording and amplification. Included are notes on modifications to musical instruments, phonograph horns, recording diaphragms, and reproducers, as well as notes on various chalk telephone and electromotograph devices to try in connection with recording. Also included are references to works by Herman von Helmholtz, Lord Rayleigh, John Tyndall, and other authorities on acoustics. One drawing involves studio arrangements for making kinetophone films and recordings. Another suggests making a hearing apparatus for the deaf. The entries from 1916 relate to Edison's research for the U.S. Navy during World War I. Included are notes that propose methods for detecting battleships and submarines, taking infrared photographs, and cooling machine guns. Other entries pertain to trench warfare, combating chemical warfare, bombs, air reconnaissance, inter-ship communication, and possible means for disabling submarine periscopes. The front cover is marked "Telephone Recording Navy." The pages are unnumbered. Approximately 135 pages have been used.

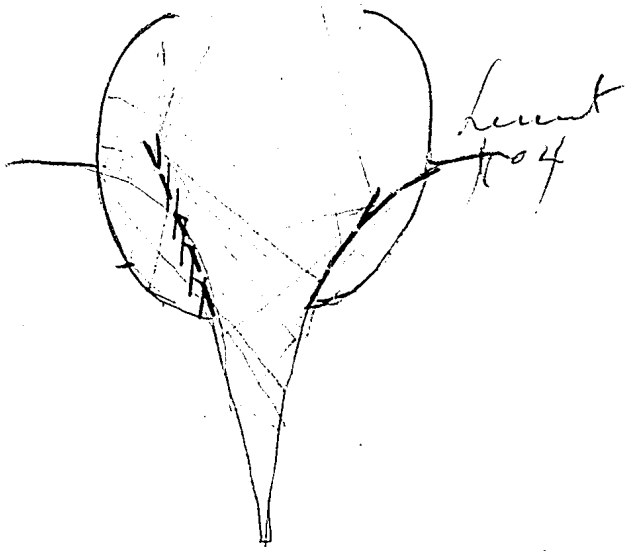
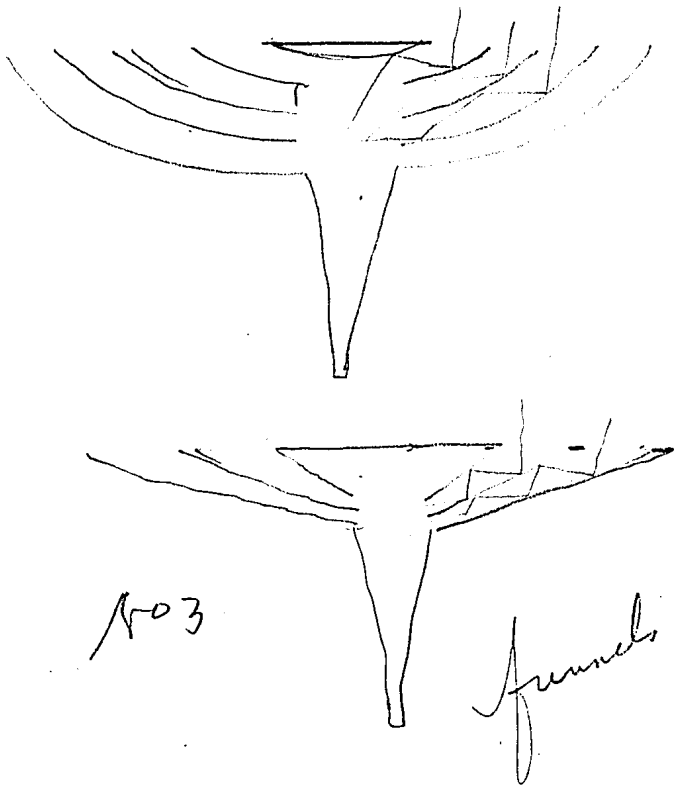
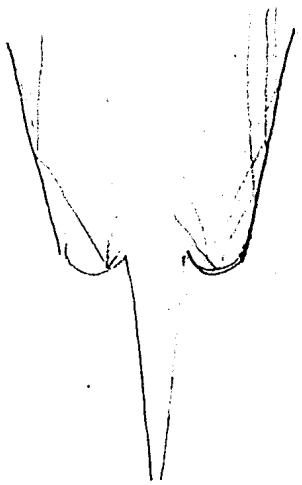
Raleigh says a hoop
Membranes is stretched on both sides
by sound waves on this
membrane ~~was~~ is sensitive but
if its big enough for wave length
to form a shadow. its sensitive
perhaps our Dia recorder
should have a shield for
low notes-

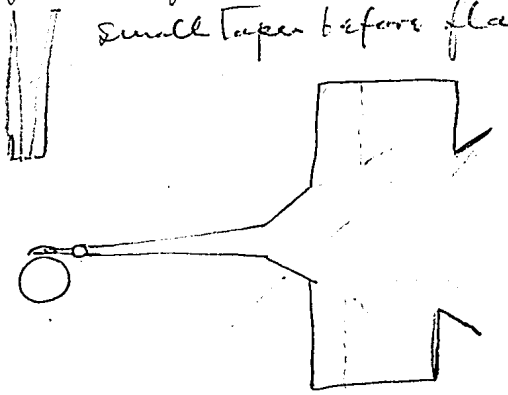






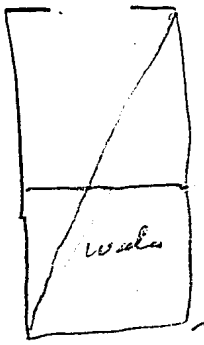
get glass funnels

small Taper before flare



Sven Chamber Manhegan

Resonator of this is Middle C

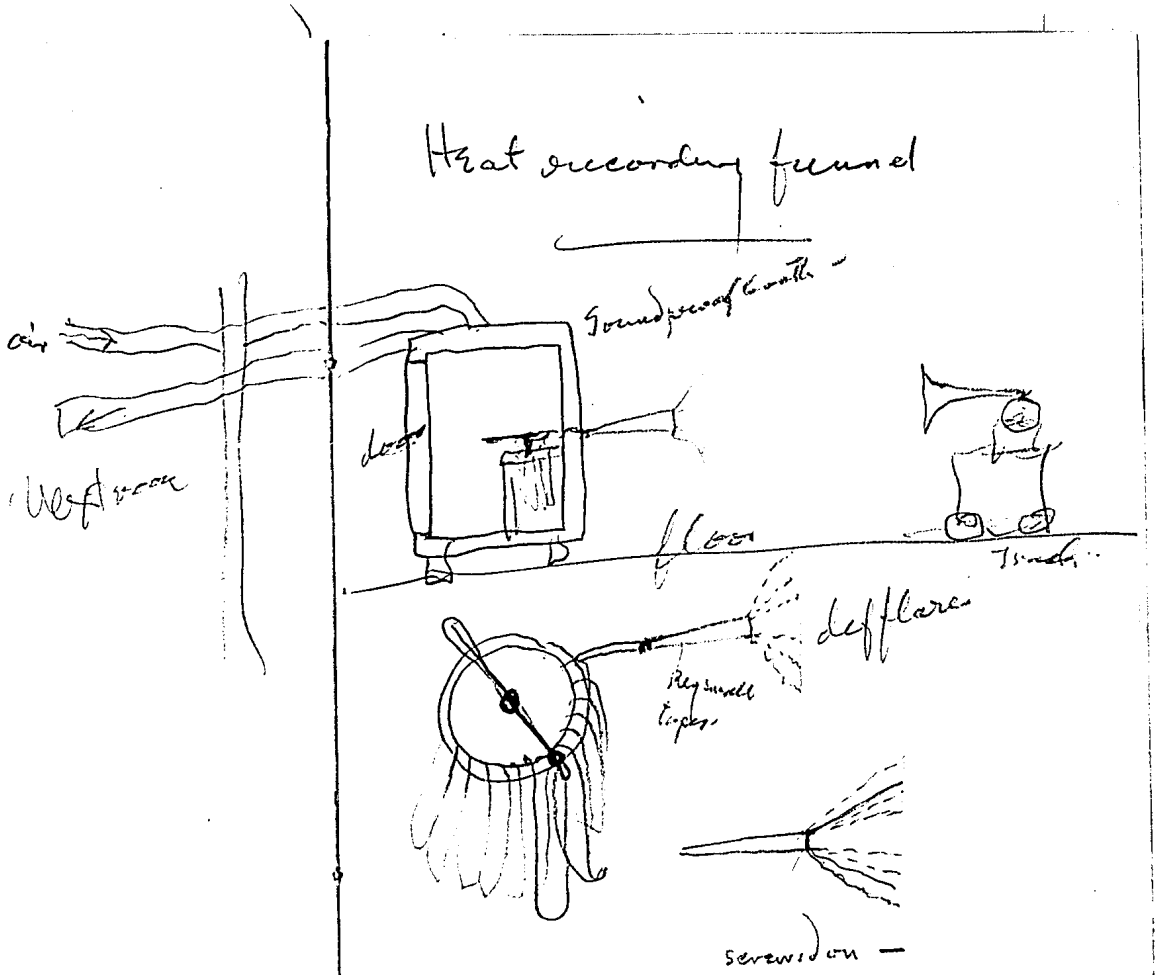


pitch not altered by moving the Resonator

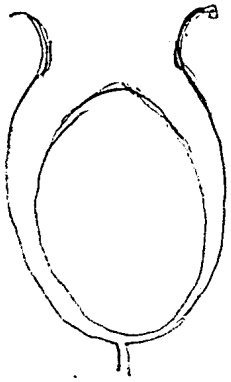
It depends on The Volume mainly & moving does not Change the Volume

For substitute for celluloid
Insulation -

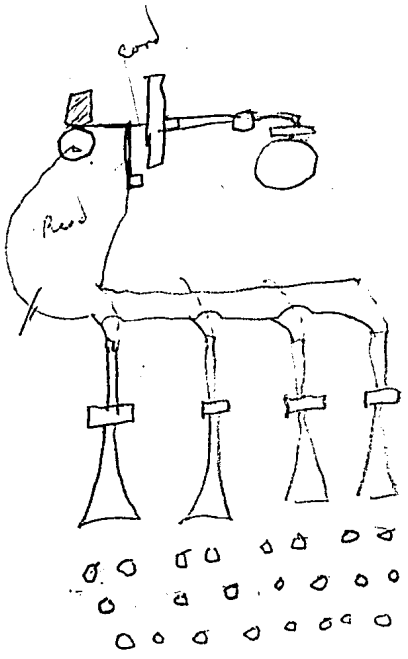
Make semi hard rub -
Pure Para - Sulphur +
Load with pure
Paraffine -
+ Vulcanize -



Heat recording funnel
air
Soundproof Earth
Reflector
Reflector
Reflectors
Reynolds Tapes
Television



In winding magnets
use the accelerating coil mechanism
to give less retardation —
or other modification, better
Remember our old Induction
Coils Spark depended on modification

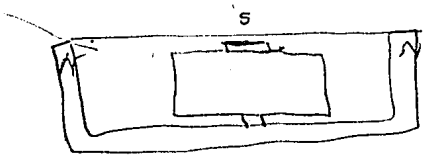


also accelerating —

Retardation when
damper

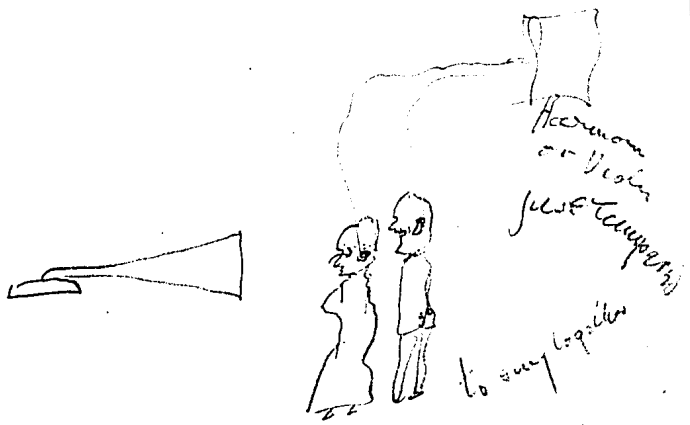
also Carbon transmitter

best Thing



NOTE

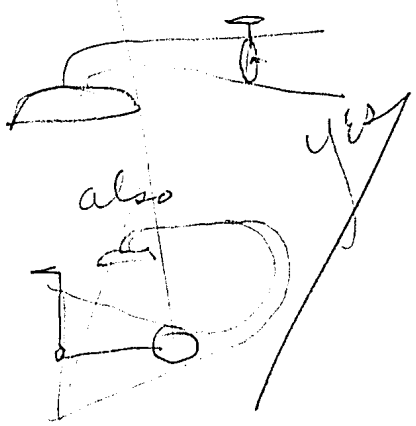
Diaphrms fastened at Edges, the Sound box must be same Coef of Expansion to get even results



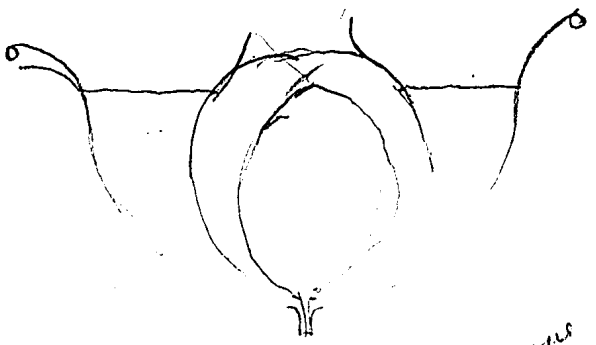
Diaphrms with fixed Edges

Cupric Cellulose
Infusible Condensate
Condensite Dust Vapour
Leather - same coef of 6/4
Nitrocellulose - Celluloid
Viscose - Glass, Mica Selenite K
Electrolytic Iron Ni Fe Cu Co
Ag Al Zn Cd Sb
Oriental Crepe - Silk
Shellac Bd - Japan paper
Gelatin - Casein
German Silver - Metals Langer Dia

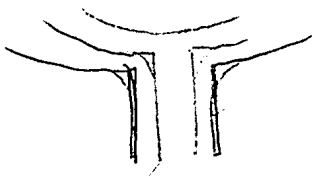
Did I patent /



Use taper like small part Ring found

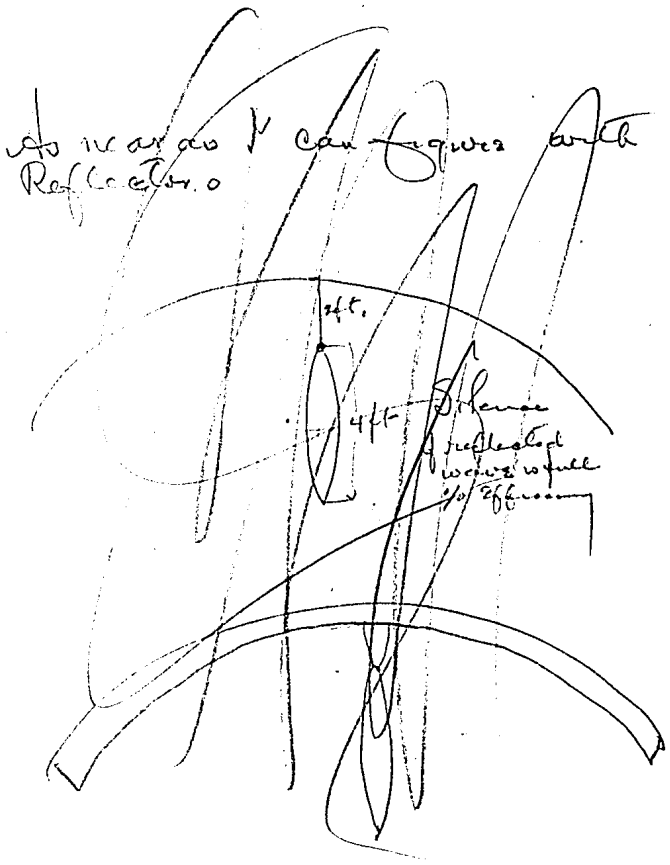


Possibly only one

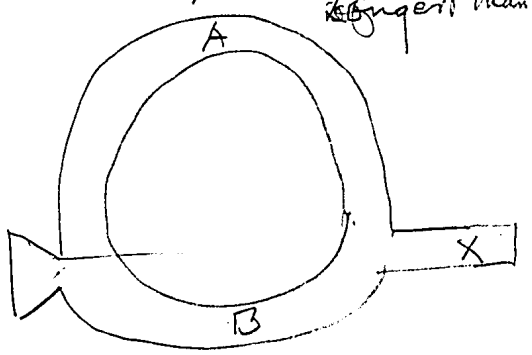


500/1000

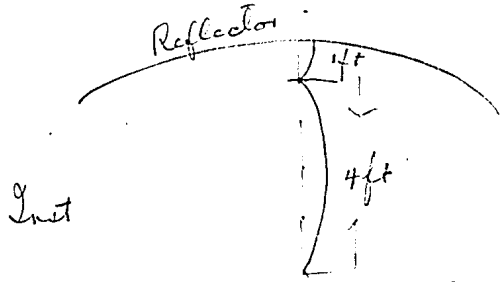
350/1000



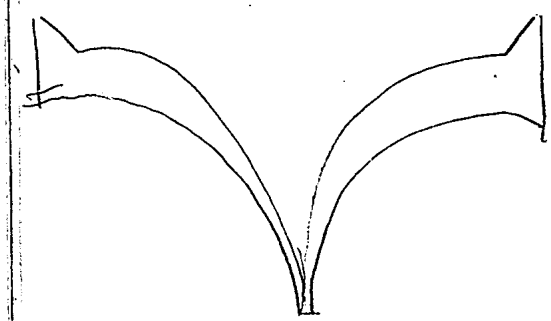
A 1/2 wave length longer than

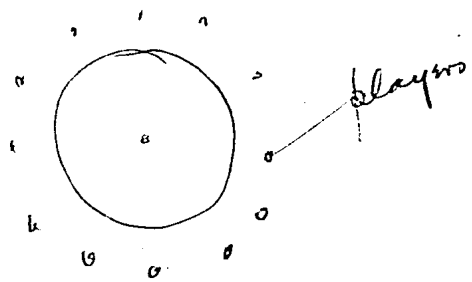


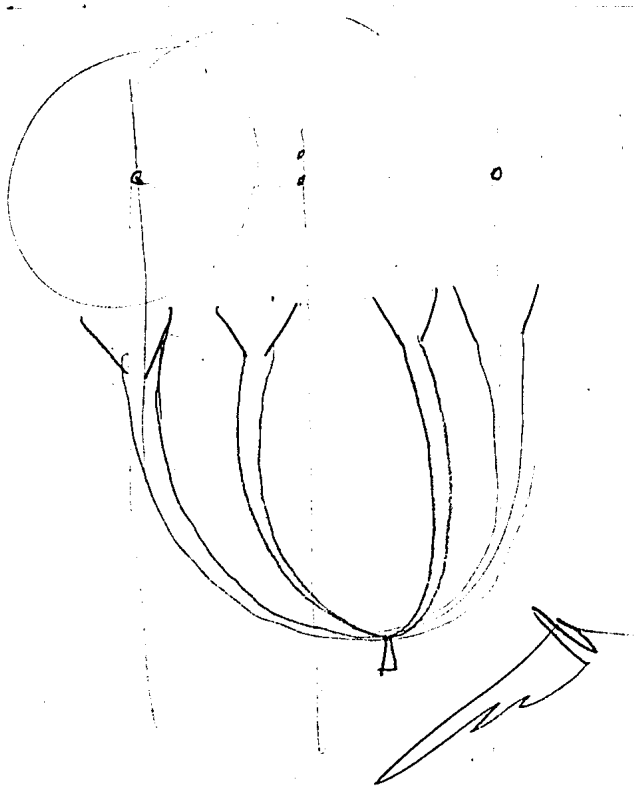
No Sound heard at X



If 2 4 or reflector from
distance 1/2 wave length
get Silence — 1/4 W.L. or less — of 64 Vib Sec
~~Doublet~~







Try Cork dia fastened at Edges, think can use it 1/16 or 1/32 thick + plug holes with wax, Etc -

Test Chowdemans Wax records

Get his past tests, then go over all & pick out most attractive ones - purify all materials, filter good & then Turn & Knock for smoothness then rough & record with 100 thread & Reproduce to get ocean Electrical qualities, sticky surface Etc

Check Telephone
Look up in Note books past ideas on this subject

Jyndall Sound '19-

from Chloride Ca with Carbonate Na use of get firmer Carbonate than by precipitation,

Get up good floating Scheme to dejelatinate or Mercuric Iodide & get it liquefied & Clear —

The strength of sound depends upon the density of the air in which the sound is generated hence in a steel chamber under air pressure! We could get much louder records
Cold room best for recording

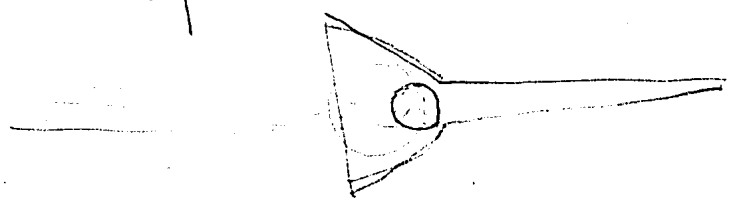
Phono

focus

Rubber balloon

Wooden

The sound wave is retained in back part of balloon hence sound; produces a focus —



Replace with the wood ball in $2.50 Duo Con [illegible] focus — larger ball + Cotton.

Try Sulphate Na &
Sulphate Magnesia & only
Na Cl. — probably get
Ox Mag Ving fund —

Oxides of Fe. Ni Cd Cu
Sb. Col

Try Lithia Carbonate & only
use water on chalk

Or Mixtures of Sr & Li Carbonate
precipitated together or
by fusion —

Perhaps KOH dissolved
in Glycerine used work
for working Eng chalks

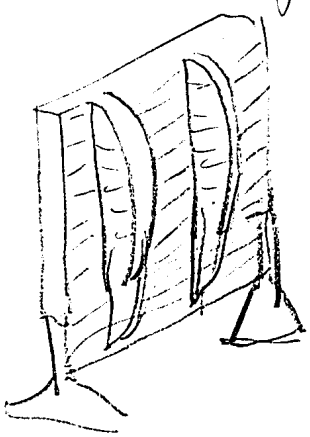
Harmonics increase in power
in a piano the harder the felt.
with hard body the fourth
partial is 3 or 4 times
louder than the fundamental

Tyndal 122 pages

Get Lifer or make up
Whetstone or Lubricant
Lets work on Ground

The Chalk for Eng
probably must be
Anhydrous. Treat
in Water or KOH

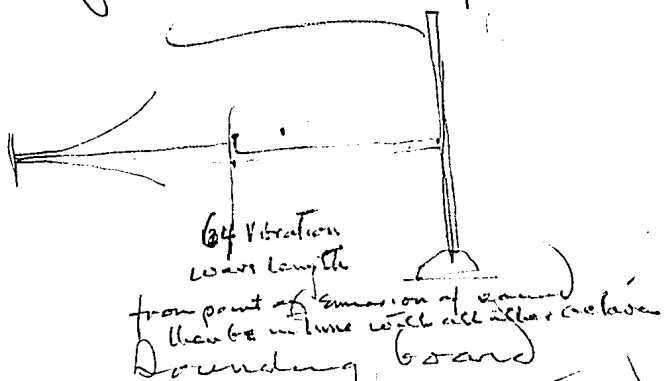
for sound reflection
Use Cast glass —



Etc —

Also — Sound board
with felt shutters on face so
it can in 1 second be turned
to use a reflecting board
to an absorbing no reflecty
board — a Conductor note
sounded with sustained
shutter will show change
of quality Compressively + leads to results

Expert with singing
the Violin playing the
Melody except on some
songs —
Cello + another Instrument
may have to play
def — or accompt —



Sounding board
must be picked in a Tuned
position.

The outer Channel of the
Ear resounds to
Notes of a Count
3000 per Second
Dogs which hears to
Music are particularly
Reaching to 3000 per
Second —

Look out for d
perhaps its the
Sensor Company
+ not the Country
or both —

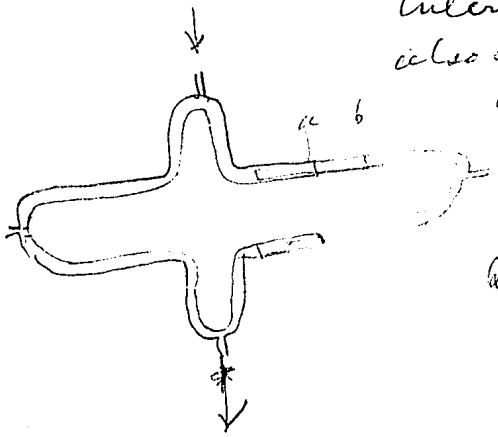
Wheatstone says only way to [illegible] a piano Sound Board is to place [illegible] bridge. + midway to treble + wire rod 1/10" dia or [illegible] rod 1/2 to 5/8 dia,

Record with which it was done —

Buy an old piano 50 to get the Sound board —

Make this —

Tyndal 261 —



interference when a minimum

Centers

1

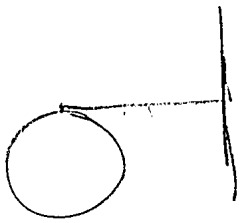
see details

Send for Longs Catalogue —

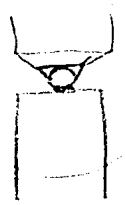
Chart [illegible]

Sizes

If we use hard Carbon in Transmitter with Duo replay it will have very little movement hence the Diaphm may have to be made larger diam to Exchange Amplitude for power If 4" used with set 4 times the previous & 1/2 the amplitude but of Lamp Black used perhaps present leverage & diaphm will suffice

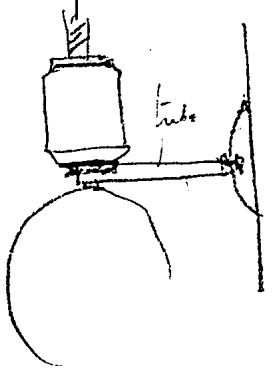


Thank Pin shaped for tube to stop bending

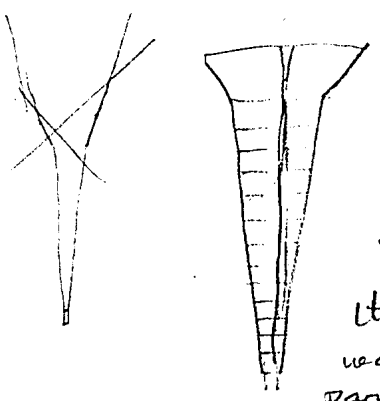


Should use a diamond tool to turn with very fine feed '2000 to inch — for Chalks

Diaphm should have a Cone

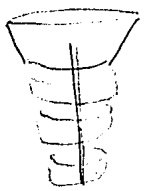


Thank Aluminum or Thin steel or perhaps glass



Thread by using that funnel will become partially to warp

Make funnel Cut up in such lengths. Then put together so 003 spacing between each section



solder strip

supported Column of [illegible] + reinforce coupling

perhaps a lapped wound with flat band do same thing

Leak where band Edges Come

Apparently should have cartridge joints on phones work expectancy near recorder as a leak makes the long funnel - at that point responsible - may subject to any to the high notes for just same a leak 1/6 inch from the diaphram well reinforce the 4th overlap of Middle C 3 of C'' 2nd of C''' + 1st overlap of 2048 C''''

Hunt up 2 or 3 old Enclosed Rubber Chalk telephones used in England for test of Length - time chalks used to measure OK a operate

Looking up old book find $SrCO_3$ 12 hours in Water 3/4 Hr Nitric in chemical washing - remark that typings used thumb test 2 for 3 drops

---

Try in Mounting Chalks to dampen with Various liquids,

Water -
" a glycerine.
" a KOH
" NaOH
" LiOH.

Try making a chalk of Mixtures of Ba Sr Ca Carbonates —

In my old book I speak of Tungstic acid as better for Chalks than $BaCO_3$ takes data KOH. & has low scratch Says $SrCO_3$ twice as loud as $BaCO_3$ or WO_3 —

Run Expts on WO_3 & Tungstates,

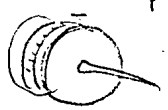
I found 200 clinks press on $SrCO_3$ best, for the sign of Cylinder chalk

Pneumatic on WO_3 Cylinders permits use of acids to wet, SS Thus big lead ! !

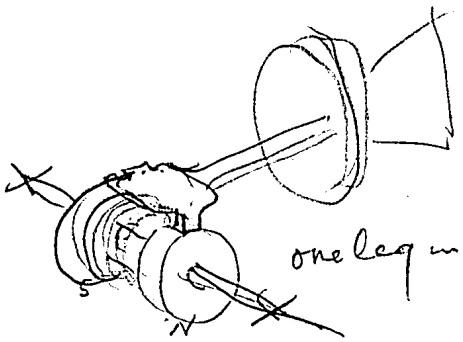
Try Mo_3 + CrO_3 Molybdate & Chromate - with acids - Sulphate Barium & precipitates the most in acids

Try arsenic & fluorides

Make Emq cylinders of metal
~~many~~ many of them
then coat with films,
acids & nitrocellulose
glues, fish glues, inorganic salts
& other. Lacquer & gums
of films — Shellac, Resin
Lacquer, Cleaners
Cellulose in Lacq, Thinners
Cellulose

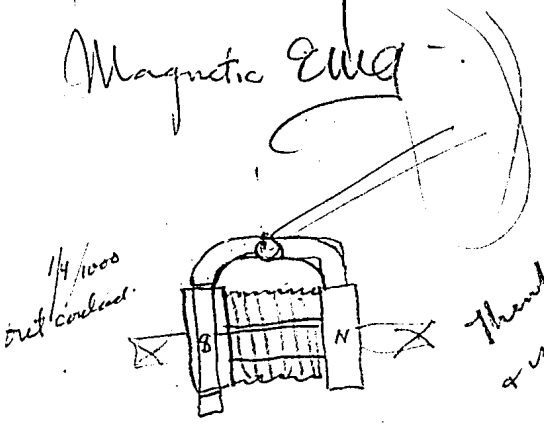


Metallic with 1/8 wide
plastic strip
then can put
strips of paper
between pen & this & marks
quick test of tolerances



Permanent mag

Magnetic Emq

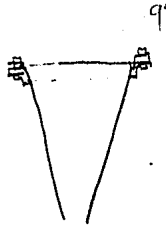


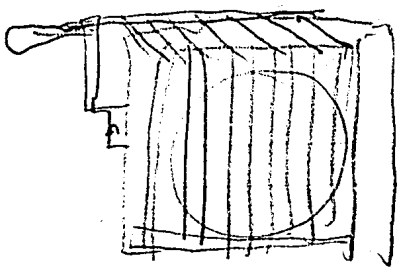
Emq - in theatre
Use the old Diz
Dia use wood
& put it under
great tension like
a piano, to get it
Rapid — S
1

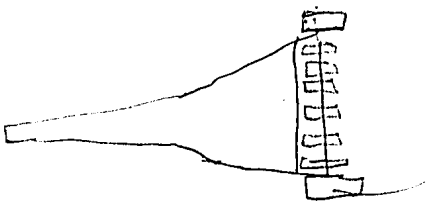
We always used Emq
Dia without tension
& they were dull &
flabby whereas under
great tension they
are as quick as the
Quartzoe ones

Get Reynaults works on
round of rubber
in England -
It has all the stuff in
& accurate
Drops in Ear Syringe (
Gold Beater Membrane
Shrunk at edges
is more sensitive than without

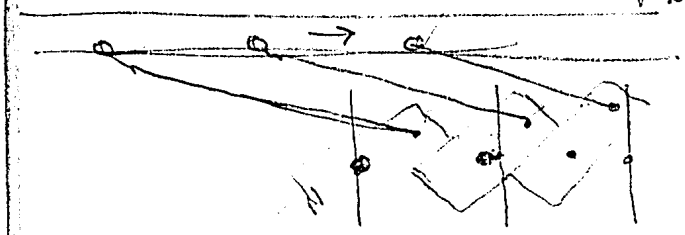
This is Contrary to my Expts
Try it



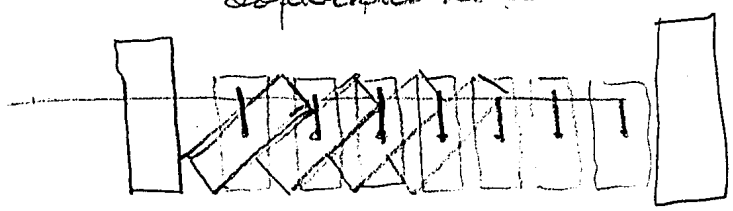


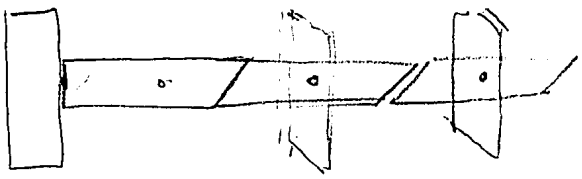


Thus can (by) on separate stand so not to Links — duplicate if necessary to adjusting

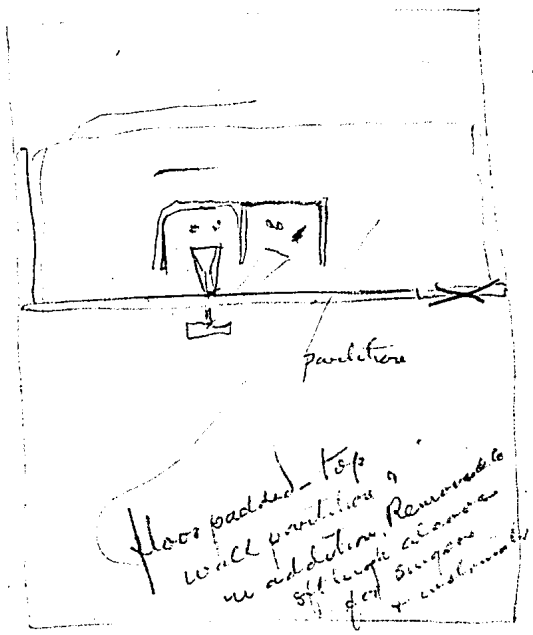


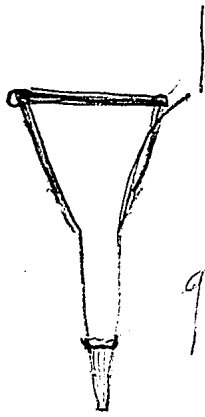
felt cloth shutter for modifying Volume of Opera sophisticated

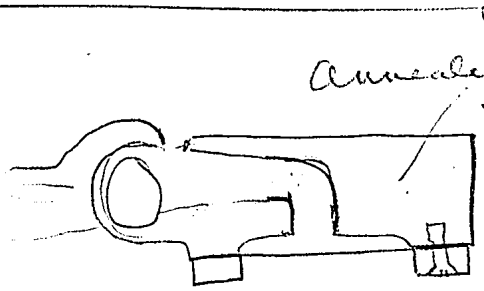




& so on felt about 1/4 thick Expt as to thickness







If aluminum aluminum used
Make box of aluminum
If steel use steel box

The Vic have no chatter marks -

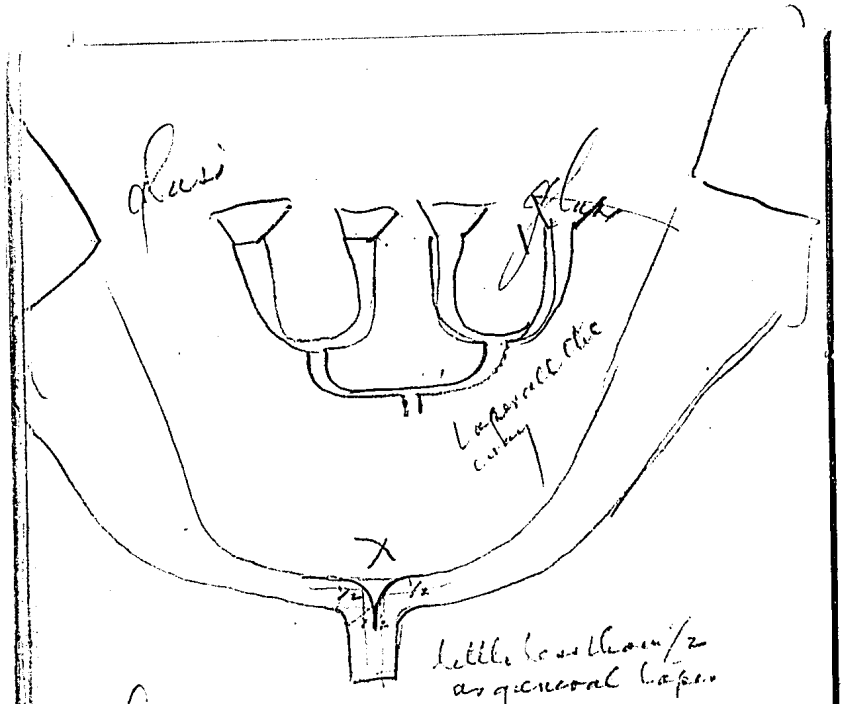
Suppose we try after record made in white wax to get a ball exact size of record temp say 1/2 or 1/4 smaller
Mount on original weight lightened to weight 1/2 oz -
Then add long spring on to give pressure -
Then start disc and run at very slow say 2 Revolution per min this will polish down Chatter marks & Bring perfectly no weight or Mass but only spring pressure & very slow it will not hurt top waves

Try grinding an Ivory Celluloid with Vienna lime

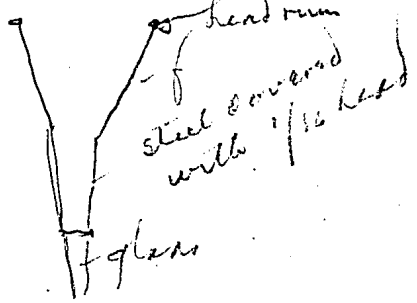
- Shew to myself Practical & Can be done -

Try dipping Celluloid Point of Ivory & Reg dip & remove -

also grafting a heavy the Ivory Celluloid of see of Clam & Cap bed point -



Think this better than Wedges as there is no Expansion at X to make a wheint + lose power



In case it is found that glass is best despite it will be necessary where fixed at Edge to make it longer in diameter This will reduce amplitude very much + only way is to increase the Knife hatching leverages. A glass box would probably have to be used or steel behaviour next to it on Expansion —

glass 00089 nearest,
Cast Iron 00100

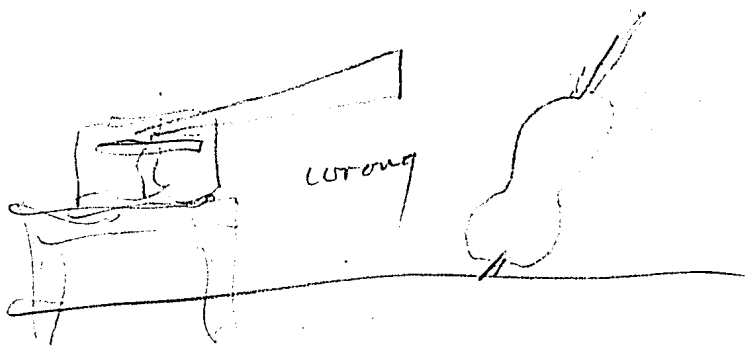
Steel box
Nickel Steel, Etc

Wood has 1/2 the Expansion of Iron glass,
Perhaps paper Tin good with wood box

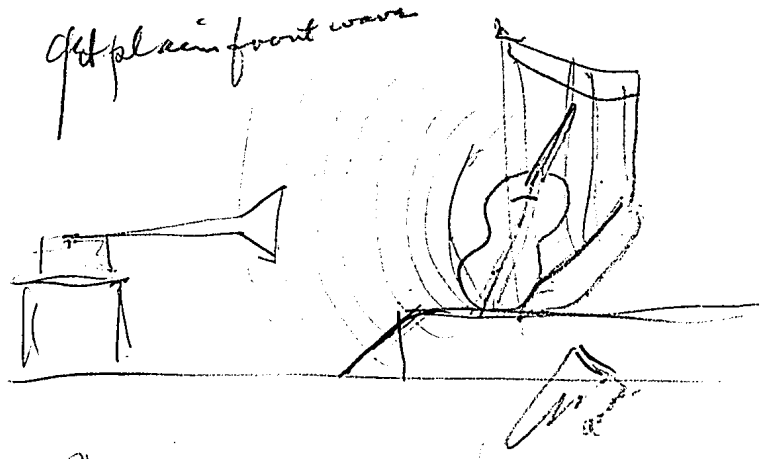
Porcelain less Expansion than anything — This is practical for a box

As I get the Elec action by rubbing fingers over X ray cards & also fingers over a metal —

Perhaps Canned porcelain or other fine grain porous paper and then coat Elec metal of platinum - Lithographic stone Cambric highly polished & straight edge —



get plain front wave



In piano the bass & overtones respond to the treble or high register is abnormally loud

Use tile lead on end of hammer as low as poss to get

The tools as if to raise the tone of low notes & diminish high it wants a larger clear more emotional tone the high & slow hammer to get full strong bear then in mind by fastening at Edge & check did it work limit vibrations for strong slow & Chopped high —

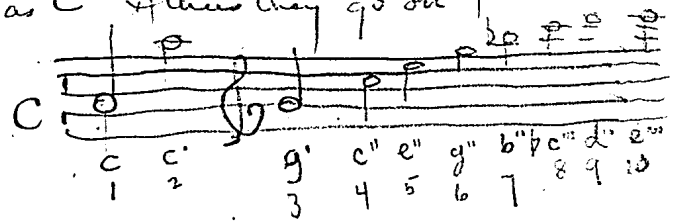
The 1st overtone is twice that of fundamental — If fundamental is Called C then the 2 overtone wave will be C'

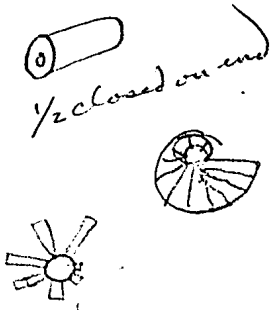
2nd overtone is the fifth of this octave or g' making three times as many vibrations as C

3rd overtone is the 2nd higher octave or C'' making 4 times the number of vibrations as C

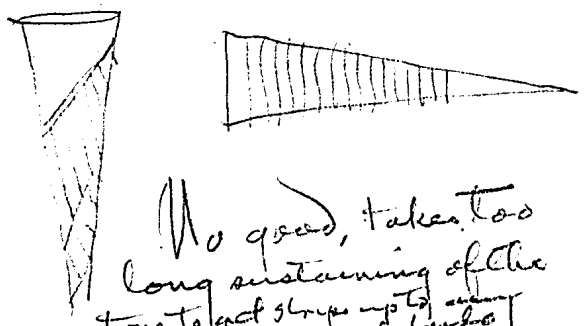
4th overtone is Major Third of the second higher octave or e'' having 5 times as many vibrations as C

5th overtone is the fifth of the 2nd higher octave or g'' making 6 times as many vibrations as C Then they go on





arranged to funnel
only a certain length –
as to strengthen vibrations
in voice & not the fundamental –
funnel for Contralto qualities
for soprano,



No good, takes too
long sustaining of the
tone to get strips up to
anticipation

Strip made of seperate sheets –
Capable each of vibrating seperately
& used & wound up to make a
funnel –
Some strips so in tune with every
note just entered set in motion
vibrations & quality

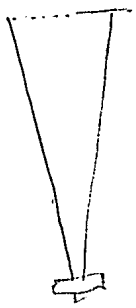
In above Connection only
can Column get quality of
Tone as more in detail –

With a fork the resonant
box the waves of the great
takes time, if one is only
1 vibrations why the depth

Hence no hope for tuned funnels
etc except with air Columns -
~~then there~~

Helmholtz page 67-
says a diaphragm connected to a
bottle 6" mouth 4" dia Long - Diaphragm 1.93 dia
rubber gives a certain fundamental
sound (C) so on tone with
C of same sound. Sand Grains
thrown to edges,
a 2nd circle showed .75 Each
dia -

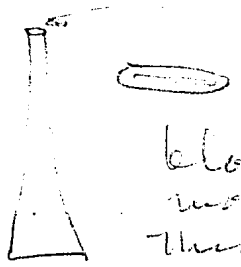
It may be we get some
bad notes when the
prime tone & over dia
is reached & that built up
Result up dia as the bad



Changing more towards the
mouth of the funnel
deepens more towards the
tone -

I think we could adjust
all our music by an
adjustment of expectations (also
they use on a Camera -
by this Diaphragm

To find tone of funnel
by Diaphragm



gives no
overtones
at all -

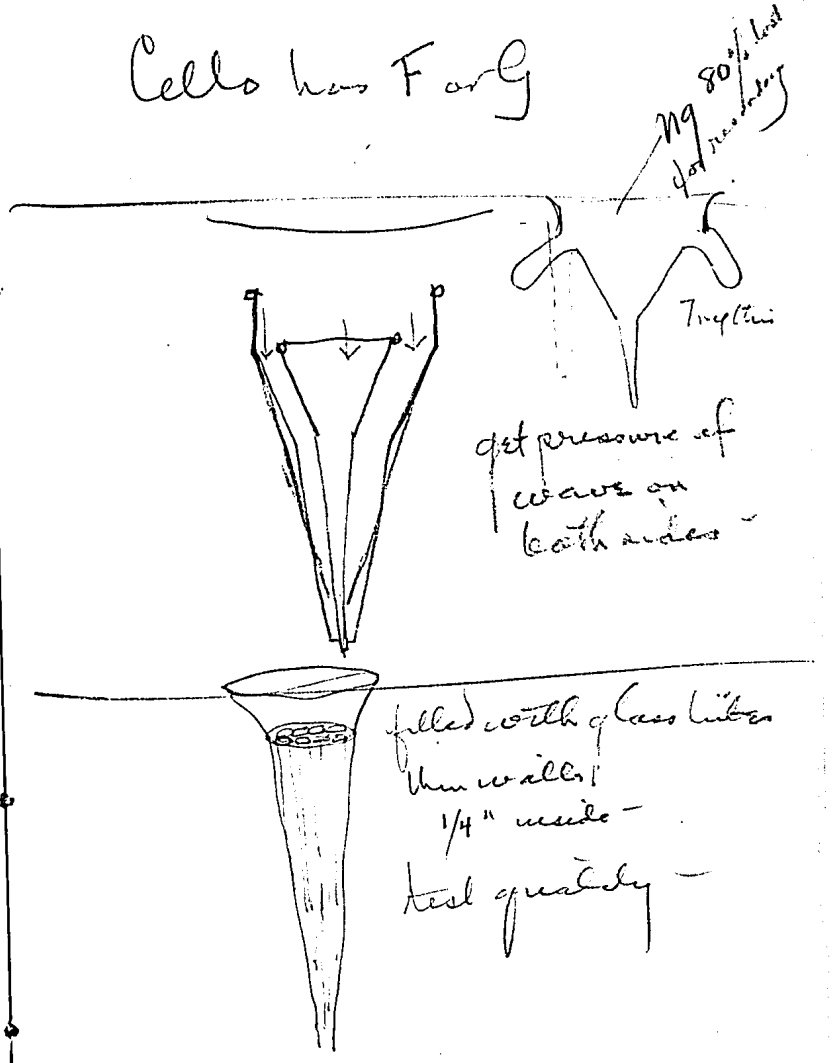
blow across
mouth
Thus gives

Helmholtz dampens Piano
string[s] to [illegible] wooden
with [illegible] and hair
brushes - perhaps several
[illegible] against a Damper which
[illegible] wooden [illegible]

Should try experiment of
loading hammers of
Piano with Lead the
amount of Lead increasing
as we go lower pitch -
to get more power and
not [illegible] strings which
are [illegible]

Helmholtz says all
Violins - have note
of [illegible] one an Octave
[illegible]
General C.
Walter Lockhart

Cello has F or G



perhaps when using a diaphm
fastened at Edges the
Diaphm should have greater
Coef of Expansion than box

then both heated to 150°Fah
+fastened. The Contraction of
dia would be greater than box
& it would be drum tight.
& wd would not be tracked
by due getting of Cabg
It would be less sensitive
at 60 than 70 Fahr
& than in box of which
temp Calculated to
get any Desirdoreness
Not required,

Cup & Diaphram Material

	Coef Expansion
Al Cast	·0022
Stl Cryst	·0011
Brass Cast	0017
Rolled Brass	0018
Copper	0015
Ebonite	0077
Flint Glass	0008
Iron Wrot	00116
" Cast	0010
Mg	0026

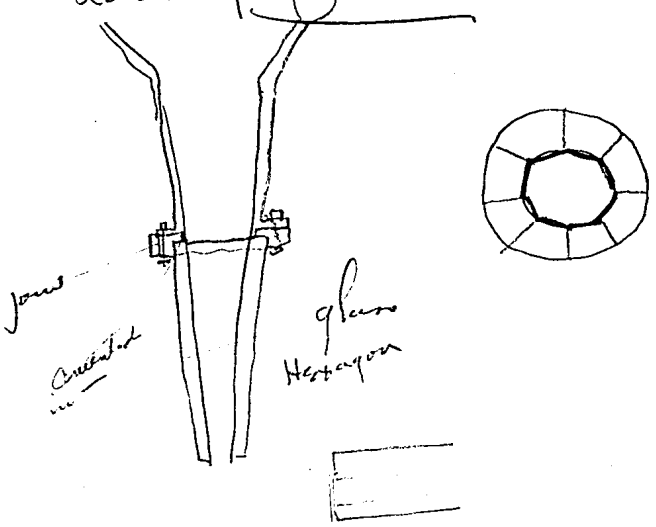
Looks like Steel or porcelain
and Zn Mg Al or Hard Rubber
Ag

Speculum Metal —

3 parts Copper 1 of Tin &
a little Ceramic Very Brittle,

Probably good for End of
Funnels but takes very fine
polish & Hands its anamorphisms
Look up further —



Possibly Hand Coal Tar pitch coated
with film dope having Camphor in
or not will deform under property
regulated heat & cool as
substitute for Celluloid Quick mounting
Possibly Other pitches also
Shellac melted with Trichp mallen
substances very sensitive to heat
perhaps can work direct with 1/8
Medium condensite —

It is probable that the
reason the other part of
a disc record is not so
clear & good as the Extra
fusion for the Knife due to
higher velocity of the
Workers cord Tones.
& also of course to Extra
Record —

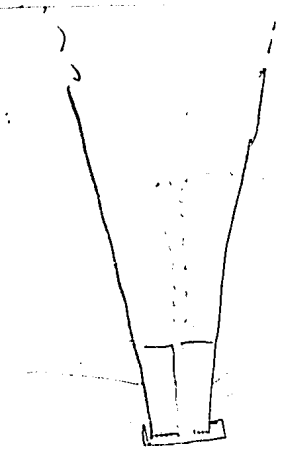
We should make so
Expts on the friction
of celluloid & copper
or dif Waxes —
Easy done —

Another cause for loss of high overtones is the pressure on the disc due to tracking. With the advance ball recorder the way that shrivels the Over the least to give normal tracking will be the most sensitive —

This can also be easily tested using a recorder suspended on knife edge the old weight with Counterbalanced as way keep it going by making Side weight with —

Some of the machine dyes may be soft wax + make them more susceptible, a large number of waxes

Make a test pure Stearine ~~with wax~~ as base



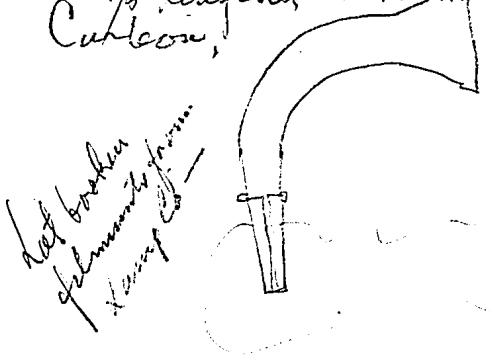
May need straight Carbon

No diaphragm —

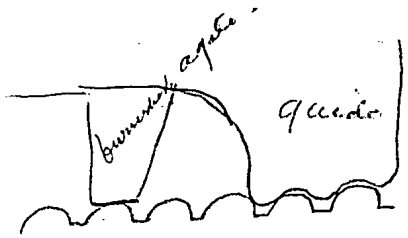
Right hand pressure

Split a la Jos's headstock + filled with Carbonized charcoal def mesh —

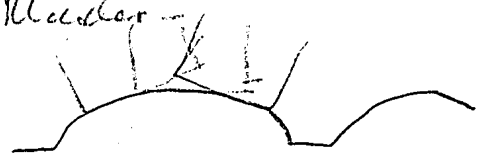
Sound waves compresses Use Carbonized thread cut in 1/8 lengths + various other Cutters,



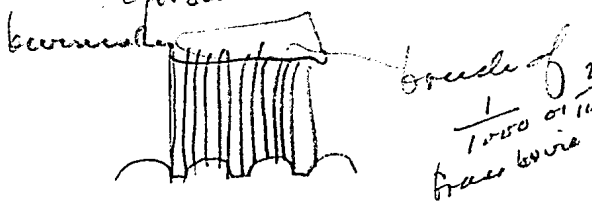
Nat brother Schmidt from Kemp Co —



To bamboo the Copper
or 2 Wooden



Gives movement to the



quite Quick -

I also regulating Wire (Brass Wound
Galvin with Brass +
Copper wire Brass
Rough or not,

1st Theory of bremalo is unequal tension of the 2 Vocal Chords

2nd Theory is vibration of the jaws throwing the air into Vibration 1 to 5 times seconds If middle C we get 256 Vibrations a ~~flow~~ a bremalo of 2 per second, the jaw Vibrates twice second - altering the resonant Cavity + varying Vol - or altering the waves into 128 twice —

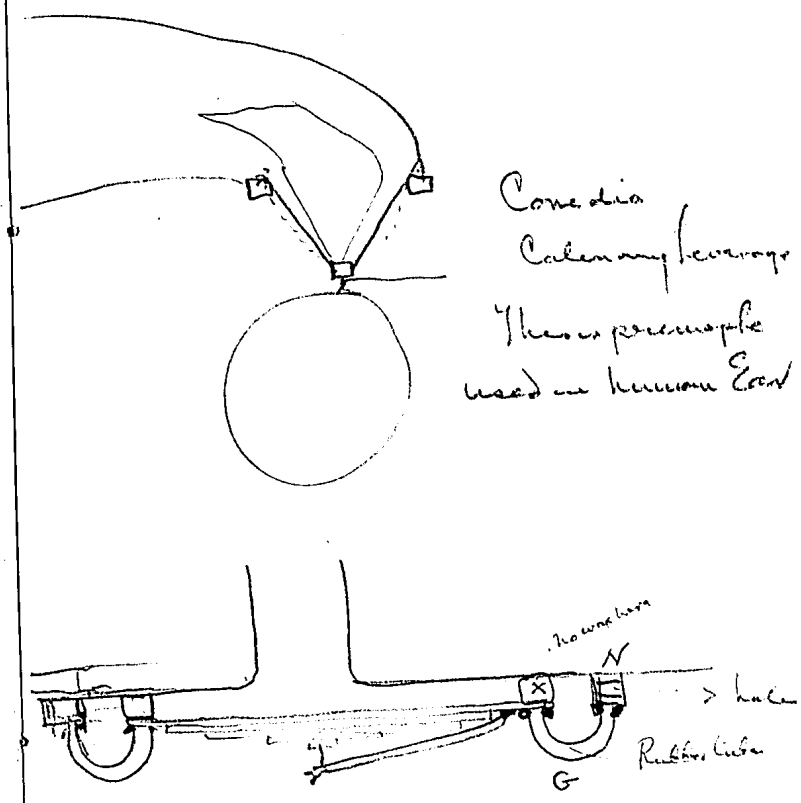
Hold the ~~jaw of a bremalo~~ engine + see if it stops

Try a song short + simple sung with A then E then I O + U, note notes that leave bremalo in Each song if detected then it must be Vibrations or Oral Cavity

Helmholtz Day Ear is tuned to notes between e'''' + g''''
produce a feeling of pain
In some Ears, if there is
any irritation which affect
this part of Ear its powerful

This is generally a case when
voice is strained + it gives
a screaming effect,

In powerful male voices
ringing forte sounds
like tinkling of small
Bells



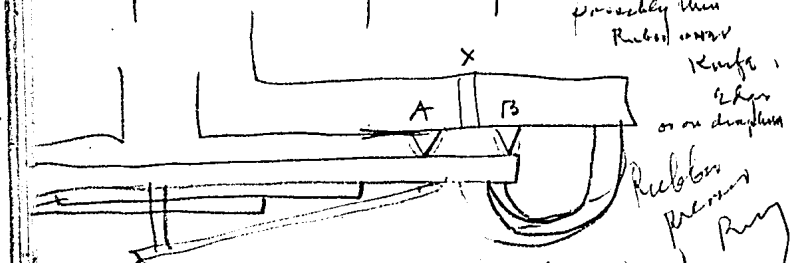
This kind of a clear movie recently
as a whole + about 1/4 inch
It held against a perfectly flat surface X
N is a ring on which other leg
G of a Rubber tube rests; this ring
has holes in

OVER

On weaver coming the diaphm goes down as a whole & the pressure against X makes a leak of pressure the escaping air passing thro hole in IV hence the amplitude is checked for high waves but not for low —

The rubber & disc must be carefully made & micro used in mfg.

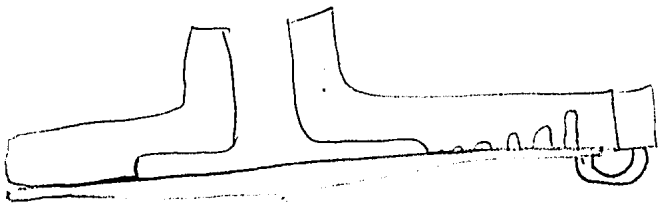
This idea can be worked up in many ways



probably thin Rubber under Knife edge on diaphm

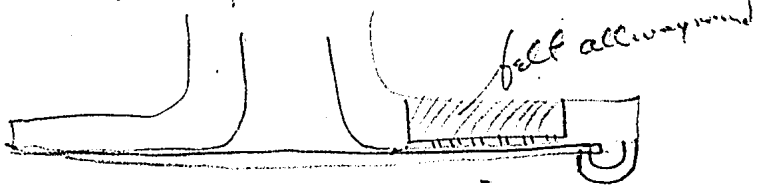
Rubber pressure Ring

Dia on two edges slight downward movement of disc it leaves A & is carried by B — thro Lets air into chamber but A+B & prevents out of holes X

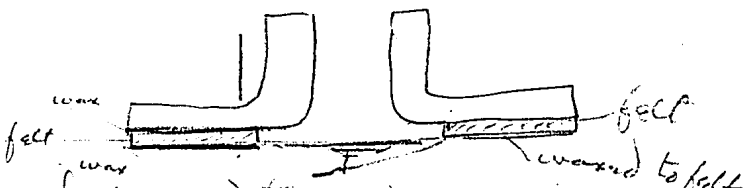


When it makes contact & Knife cutting a downward movement slightly of Cyl disc a open valve to a small groove around box & flows more Cyl Longer & less & on any thro Lowering disc

Note opening & Cover

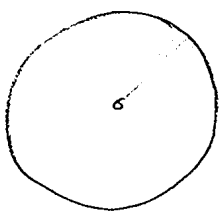


Another idea —



This makes a soft long lay 20 to 30% look through of felt ½" long —

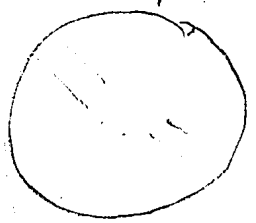
dia section of cup —



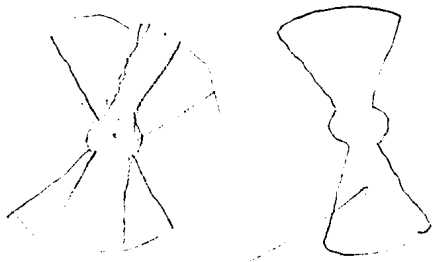
cut oblique by a razor to center + used in this

Pressure put upon this with split rubber tube

This principle can be carried out in many ways

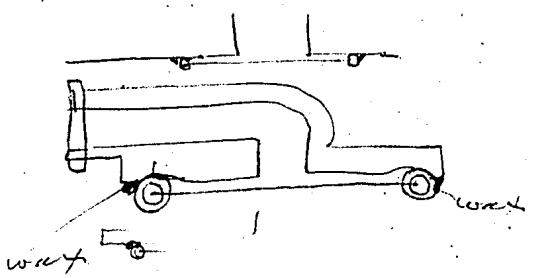


oblique cut

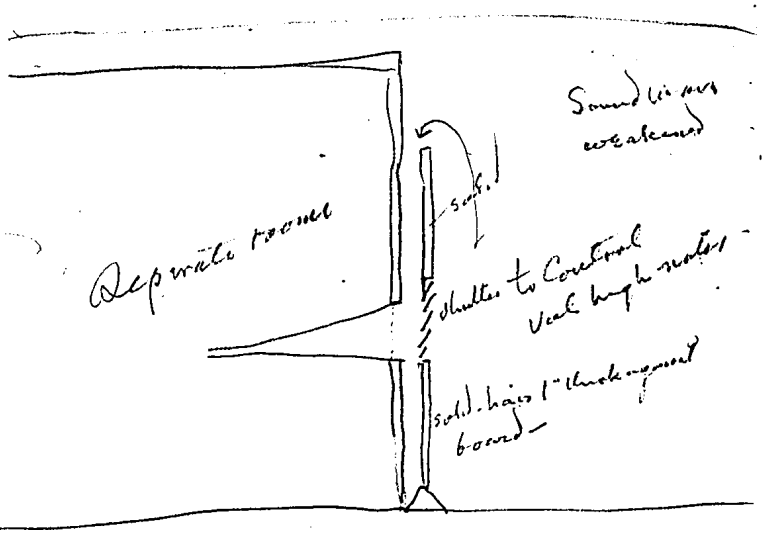


built up of sections like this paper, wire, etc.

While this looks good results are only due to ribbon & not to split diaphragm



wax
wax



Separate room
Sound waves
Shutter to Control
Solid. hairs 1" thick

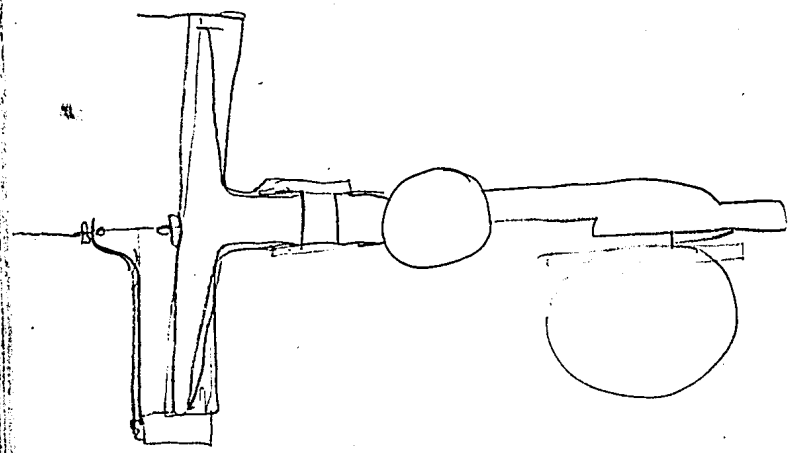
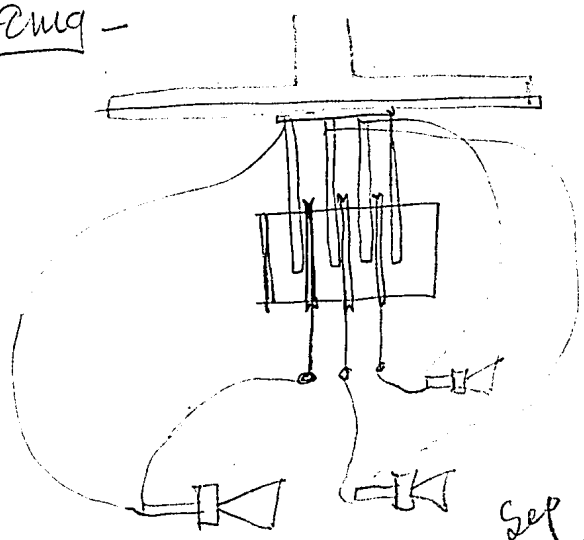
mat —
Emery - Regular Macerated
from Glass Funnel

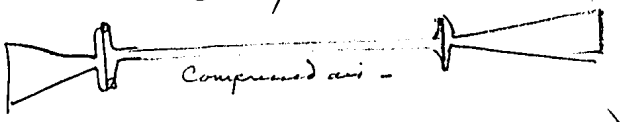


Emig –

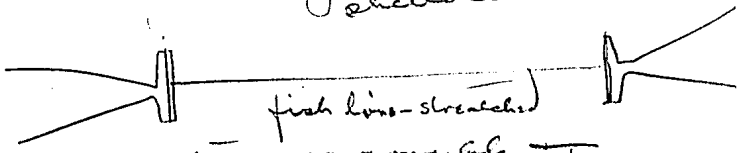


& so on Sep
Checks work

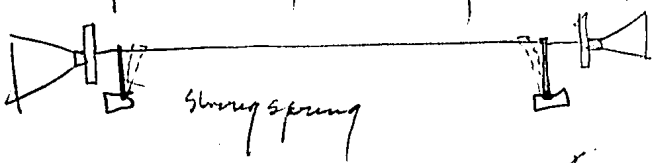
A 003 Copper steel wire 10 ft long
is same as a Cube 1/10 of one
inch, thus is next heavy loading

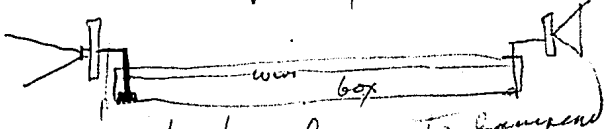


Cat gut, driven thread
shellaced –



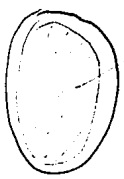
as strong as possible –
shellaced thick so it is soaked –
shellac + gum sat all over outside
5/1000 thick, then waxed shaved
Ended by longitudinal Vibrations
12 ft should be very light
weight. Measure Rheostat
very tight & assembly





box has glycerine to compound

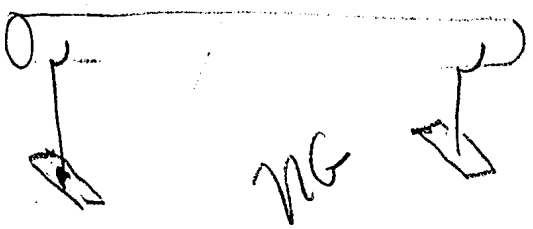
It looks as if nearly all of a sound wave is absorbed by a bag of Cowhair such thick



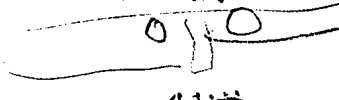
dia cowhair

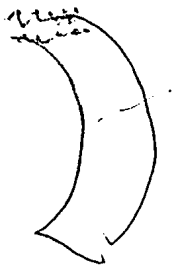
Sound waves would not rebound from Cowhair hence whole of the Energy should be absorbed in giving power to Dia —

In Recording room are Can be got up (12) Undulations thin few 6@10 ft 6X6 Inches Lead Cowhair



Try 6" tubes of Drawing Board paper or Brown Wrapping also Octagon with strips & so only sections of paper vibrate Hence would get quick response that carry over 66 Sound - stop Rebound Vibrations —





Have a Tune with low notes

Try one made of metal tubes from 1½" downplane wooden for Bass

It may be the reason we have Values on. Low notes around is that partitions funnel it two parts in tune + give big Vibration to touch of finger This degrades the Energy The funnel channel displaced to low notes + everything Else in room — Piano top slab

Bell sound maybe due to impact of sound waves Especially low ones + possibly 10 ft long box will ring maybe bell sound when 30 glass tubes inside resonate together will not + val nal would dominate passing Brass tubes — the Bell action will diminish as diameter diminishes Even 120 1/2 bore glass might do better —

Possibly = Wind instruments Could have connected to them Cavities like the human Cavities + thus give more overtones + changes gradually of instrument Harmonics

Put strip Cork under bridge of Violin —

glass fibre bow for Violin +

artificial Silk strings to bow —

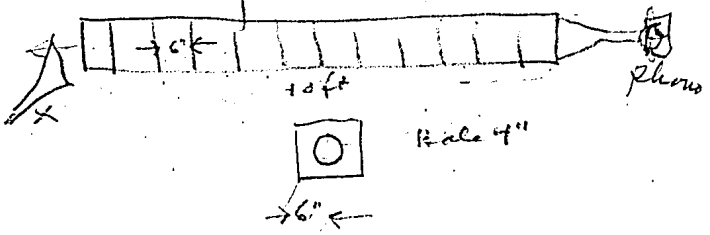
an Extra dead string 3 of them steel — to overstrain the Violin — + not used to play on — Cleaner resonance

Aluminum cover on Violin = also Sizal also the fabric from aqueous Wax used for thread impregnation

Steel
Paint strings with Condensite
Varnish a Ramdew for
Violin —

Violin - Strings double like
piano — steel strings —

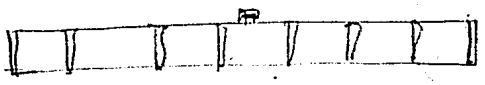
Tried today

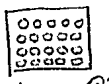


With all in scarcely hear
anything with the partitions
closed half-plaza and 6 of them
No improvement but somewhat
louder without partitions
1/2 the loudness with X found
at end as it was with
X in front rig found

Noticed when No partitions
+ box lid open heard scarcely
any Bass Everything sharp
no mellow or overtones,
When lid closed it was
twice as loud & Bass
Came right out loud + mellow
Cuts higher notes Thin,
+ tinsley —

Shows which are bad -
also 10" 6" wood box
Cuts Violin down more
than 1/2 = 2 ft. doesn't show
much barrel sound —
The whole trouble is
friction,





End pieces – ~~of~~ Scraps

with thin Celluloid + 50 lbs pressure in 10 ft tube 6" mouth or can use 6 inch pipe –

Think of tube polished inside by very little Lacquered –

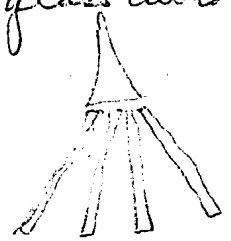
Tried today Feby 10 1914
24 tubes brass 1 9/16 inside diam 1/16 wall (about) 12 ft 6" Long

The Volume when listening with funnel was about 1/2 that when funnel was in front of phono funnel

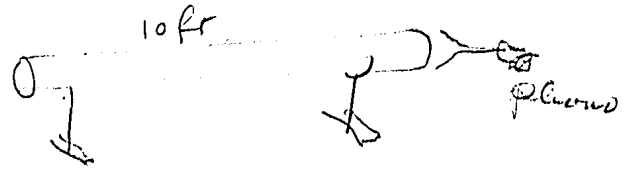
If Very much louder than 6" box with one or 2 sections in –
The quality was OK. Person spoke in air gave 1/2 the strength than can be when he spoke in funnel Voice change in case + Mellow in funnel – apparently Very little muffled + no echo or other swell + about same muffled as Humphrey talks + is more favorable for music + singing than otherwise
I can't find any Vibration of tubes – Stopped a room with ~~cc~~ carpet it was sweet again and no barrel sound

Think could go 15 @ 20 ft.

This probably by bellow with glass tubes 1/8 wall –



1 funnel 4 section of tube or 2 funnels make 8 or 32 performer



Tried drawing paper 6" dia
Listened with funnel dia
it acts about same as 6 x 6"
but shade louder & thunk
its sharp + poor.
The 24 brass is mellower far
superior for our purpose but
only 1/2 ~~[illegible]~~ ts 3/4 the loudness
but & thunk glass will
increase Volume —

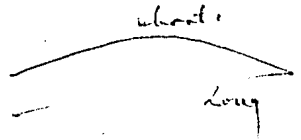
Ft Myers March 15 1914

Interpose induction
— EMG check ckt if much
internal movement in
Carbon Contacts —

A funnel to record B
funnel closed at small end
The walls of A funnel
are neutralized + closed
not vibrate producing
B walls are strong

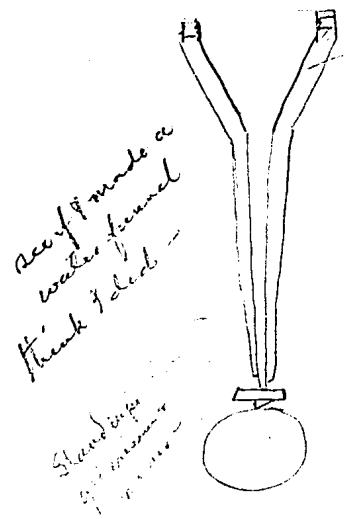
to get perfect reproduction
End of B closed when talking
a diaphragm

I noticed in Explanatory talk articulation. is better to me on Last ½ of record than first, also the singing + music is better, — Which seems to show that overtones + higher tones are less audible on long than short thick



Also it is noticed that on cracked blank has a smooth surface with few scraps — But section reveals how it is rough and [illegible] scraps Thus due either to vibrations given The Sound box itself by the waves blown Or the displacement due to the waves displaces irregularly or makes Hard rough surfaces reveals are not given certain regular displacement to face of record and [illegible] [illegible] or wax chips

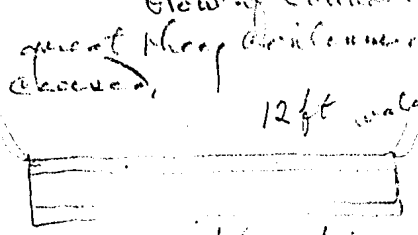
It is noticed in the playing of Reg Teachers of 1914 January to March that a scratch made to one other first part of record than the last a reversal of all or nearly precedence in



to stop movement of walls of funnel

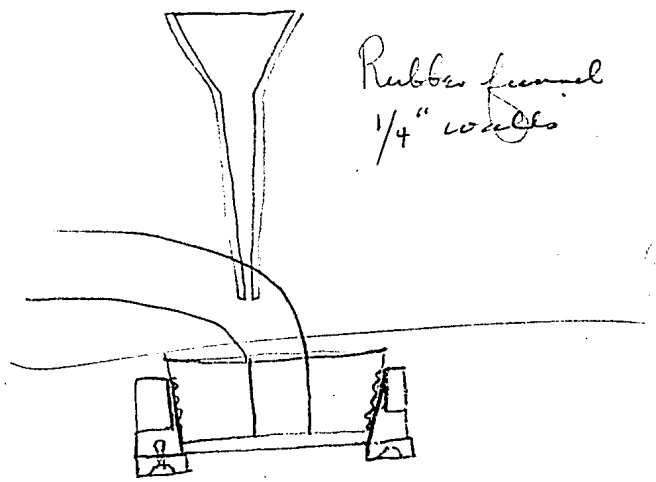
9 inches barrel Sound use Horn long wave tubes 14" plan is due to blow of sound waves

a curious in one of Reg Gramophones Sound has changed, also tone



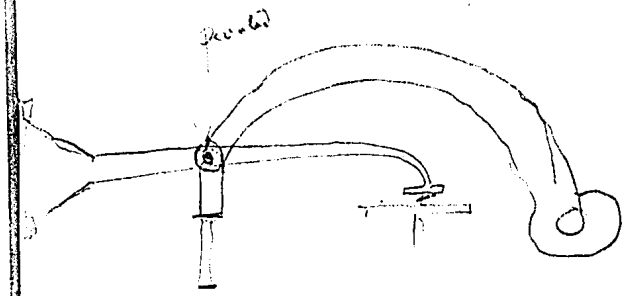
see if barrel sound

The 66 around increases as diameter of tube increases - Get very thick Shelby tube 4" a 5 ft long it, pressed inside ½ to 1" walls of [illegible] Also cast iron 1st thick - 2 together 12 ft polished inside, 4 or 5 inch inside -



Rubber funnel 1/4" wedge

Taper wedge to spread holding ring where Dia decreased at Edges to overcome heat expansion by variation the distance

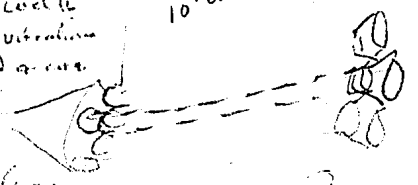


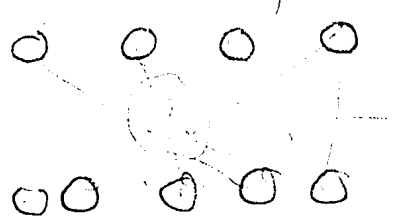
We should fix ground hammers to reduce variation high water or low water will be recorded + give proper [illegible]

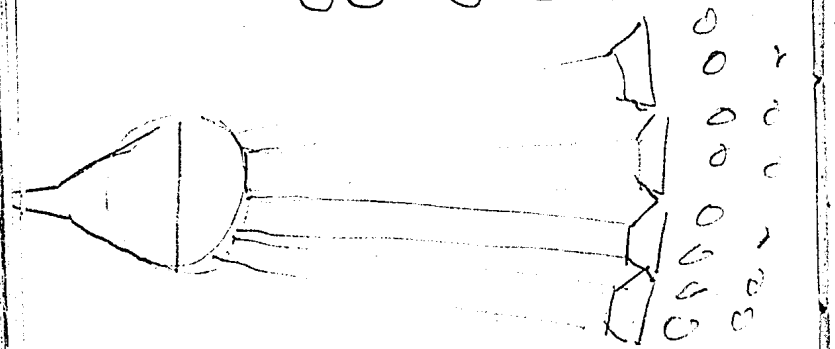
Brickwork -

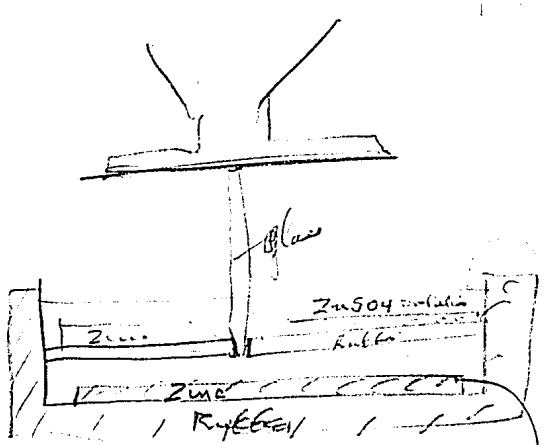
Evidently after [illegible]
of Barrel [illegible] to degas
to [illegible] walls in cooling
1 @ 1½ glass; the [illegible]
too high to record a run.

10 to 12 ft
1½" glass to Centre
10" [illegible] Nucleonics

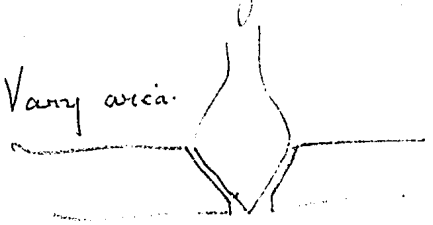




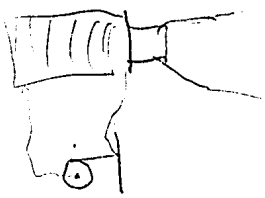




Electrolytic Telephone



Direct or Thru Coil -
Magnetic or [illegible]

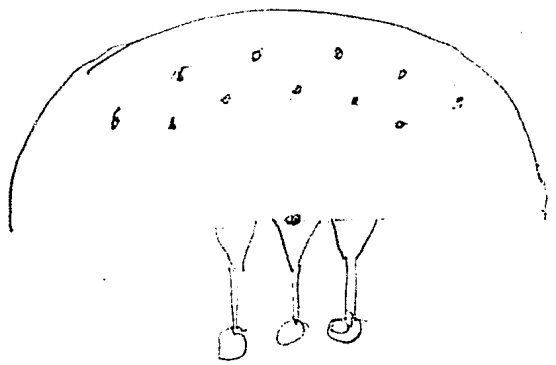


- 1/1/1 -

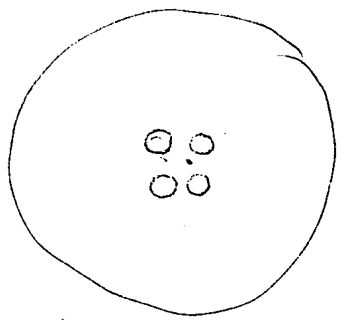
The colder the room temp for recording the greater the volume and air is where denser & more movement of particles - gives stronger waves, in a vacuum there would be no sound waves with music, ordinary Voice there might be with much movement

The paper the funnel is made of was a conductor for heat the better, the conductivity was if it received heat or cold is affected accordingly - Cones are generally best waves, or natural wood & heat from ground cannot to expansion in growing Resonance -

Wood & Varnish like music wanted Horn using wood - best shows the loudest of all the 42 funnels for recording - 9 of away from a Disc

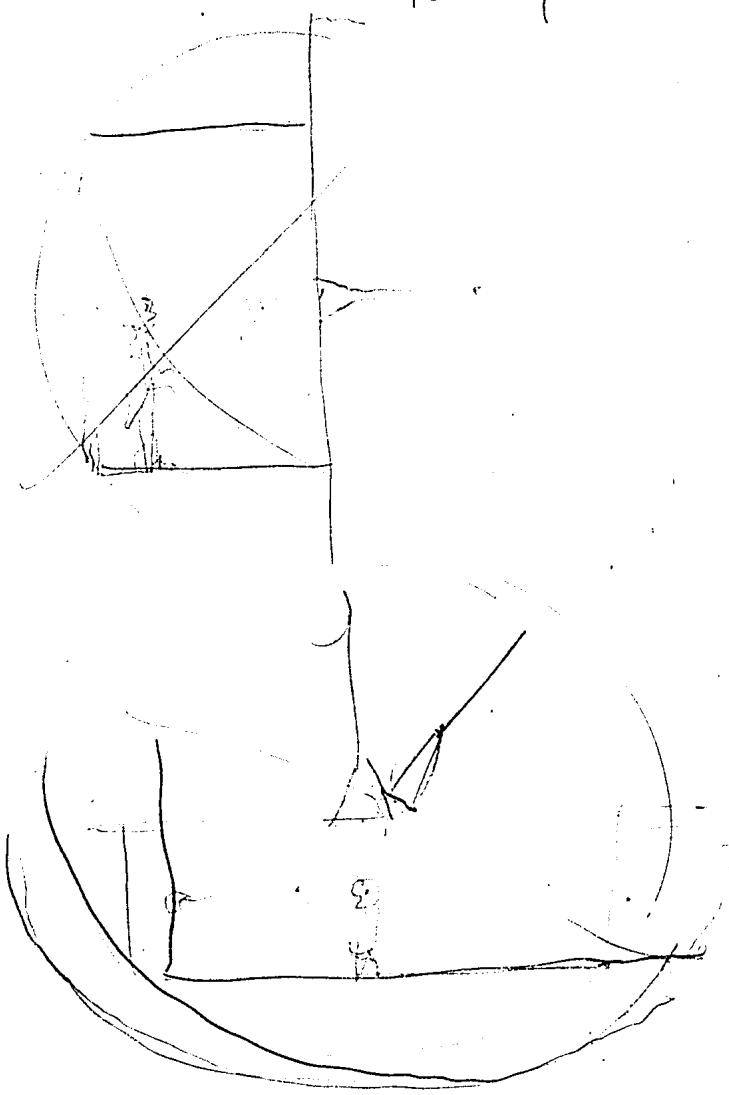


Think with the Reflector & Records equally 4 - 2 top 2 below can be taken both same time -

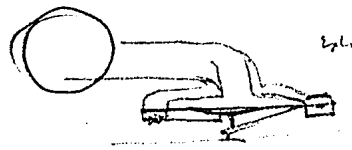


4 would be better as can have a man at each

Kinetophone—

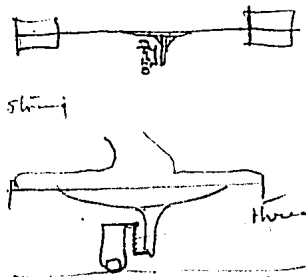


1" celluloid dia fastened at Edge—



spring to bow dia upward-so it wont jump out when sensitively adjusted—
Old style free at edges has no limit + must jump out if sensitive, Only use spring so it bows if just enough and no more —
Perhaps if Knife holder fastened to rim + not to dia it could bow diaphm upwards enough to prevent jump out

also



Cant jump out.

Films for Recorder with Diaphm fastened around Edge

Hyatts sick
Collodion
Acetylcellulose
Silk Cloth Collodionized or shellacked
Gold beaters skin
Fish bladder
Animal membranes generally
Glass flow sheets blown by Daily
Rubber stretched to limit
Disc Varnish Peula & Para taken from plate hot or use Sesame oil —
Paper - plain Collodionized or shellacked
Mica
Nickel 1/4 in - by Electrolysis
Sesame & Silicate Soda
Linen Collodionized, gutta hot rolled, Shellaced Etc.

If Animal porous membranes used in recorder, fill pores with gelatine, fresh glue with glycerine to sound well go. when water goes or dimmished Volume

When Piano is used strip it of the Case & all parts that will Echo the sound wave from other instruments & in Reflector put it in various positions to get best Effect. —

Quartette Rigoletto

Each singer has telephone Ear piece connected with telephone a clarionette plays the melody The leader who has telephone Cap gives the time or rythm all singers sing to Clarionette & Correct look by it to get no beats no singer head any other singer —

Above Ng

Navy Oct 25/16

Using Rapid heat covers some heat smoke stack of Dreadnaught to act on a lamp lay on a focus — & Thermopile with galv or telephone receiving Current transmitted

Photography Send out a beam of light as powerful as possible down any one with practical amount of electricity. Open beam then in direction of Clarionette for visible light — Use very sensitive plate with reflecting lens order to bring to a focus. focus demonstrate the plate with sequence or Equivalent Heat from Furnace — Experiments to determine best Sensitive Dye for photography Infra red.

Rock salt lenses or Fluor Spar

at 100° heat the waves are 92% passes Rock salt 54 Sodium Sulfur 33% fluor spar, 20 other things — Tyndall's tables give 3½% reflecting power

Opaqueness to 100° radiant heat depends upon the thickness of opaque substance are made very thick they may approach Rock salt in transparency —

The water vapor in the atmosphere is going to be a bug in working infra red at a distance — low humidity will be few and far between

Gun machine guns after Charge explodes Exploded Capsule Solid CO_2 or Liquid ~~or~~ to Cool gun.
or water jacket Water fed with Solid CO_2 ~~block~~ Think most practical is water Cooling ~~at~~ minimum pump circulating thru a barrell sub cooler. if large area radiators to ~~the~~ gun barrell. poly Ethylene record powder

It is probable that there are ordinary conditions which relevays appear. Calculated to use values of muzzle in absolute darkness for light & radiant heat & how long that they would exist. Could not exceed a Freyan second. Would stay or Infra red & how could these flash in the dark & detect them ships at a great distance in inky blackness of night

Think on night attack use of over & only Exploding shells that are opaque sensitive to light & reflected that ordinary light would be used to see that ships but distance —

Another scheme is to send out very powerful sound waves that for second below audibility These waves strike ship & rebound back — long Cylinder is tuned to these waves. & listening tubes used with a revolving valve to break up the waves into 256 per second or higher rates they hear over

Iodide (red) of Hg changes color with heat, Turns yellow

Infra is absorbed by water, benzaqua (bad) glass is practically opaque
White rock Salt, CS, Chloride of phosphorous passes infra freely

Telephoto Lenses

Take advantage of the greater absorption of 100 c Yards Mercury gas for reverberant heat than dry air —
Use thermo & bridge method —
Air (dry) absorbs 1 while Mercury gas 403 times more
Ammonia has 1195 —
But relative absorption where 1 inch is air 1 — Olefiant gas 6030,
Sulphurous Acid gas 6480
adding 2" does not increase as may from 1st inch readily 90% than 2nd "

The time elapsed between time waves sent out and return gives the distance of the ship —

Another way is to use my aeroplane torpedoes containing a charge of magnesium powder & with a very powerful camera gun send it the greatest distance possible & explode & light the powder — at same time on top of vessel have Telephotographic lenses & rapid sensitive big grain Emulsion plates & photo with the flash record heat the Nitrogen —

Any high speed (40 miles) Aeroplane Engine could be sent out to do this say 300 miles or more a distance could be used

Think in clear nights by using only the photographic rays which are nearly invisible & not using a beam or focused use several beams to give general defusion so enemy would not notice it that we can photograph a dreadnaught

at 5 or more miles if we use a Special large grain Sensitive plate. perhaps a generally diffused blue & violet rays could be used. + Exposure of 1 minute or less.

Special flypaper or bandline paper bits for spraying ground on retreat Delayer -

Ditto a Mechanical delayer like a lot of wheelborrows operated from 2nd Trench -

Try Expmt of how Effacent a 1½" Cowhair pads over the Ears is - in Cannon work.

~~[illegible]~~ boomerange photogh Camera to go over Enemys trenches & sweep around back - may not be hit or noticed - move Swift.

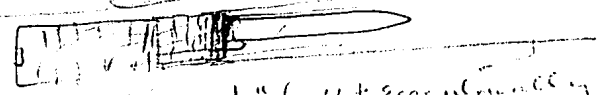
Electric boring Machine device for
boring to close by Grenades
or opening of Children Etc
The chloronk under pressure
when break their gas reaches an
Mining explosive connected —
5" hole It would strike the
deeper or rest sections
a non-poisonous gas would be
better Gas an explosive perforation
better probably — only it would do
with 25 per mile somewhere
Example melting of Ice caps by water
with explosive gas, The gas would
probably have a fog or smoking
or non open light,
We could protect by shield. till they
get in the Tanks,

If ground pressure could use double
depth center to make hole,

A large wheel 3 ft free
6 ft dia filled with gun or
Dynamite, propelled by a device below
the ground & with Electric Motor
causing it to revolve
course the wheel not penetrable
by bullets & moving fast
for queer of Expanded water
or Steam Engine,

Also an incline up which wheel
rolls & exit vertical motor but
Collapsible if Enemy not for
ward, unravelling & wound &
fired by periscope,

Wheel runs up incline



½" bullet secured by
fastened to disk
The disk would stop while
bullet would rotate on the
Eccentric axis & produce more
Effect on larger bullet, Three
½ dog Turns as usual Ammunition
could be carried.

Powerful arc light in daytime
might be an aid to vision for
Operating periscope -

Many revolving mirrors
Through many deflections of the
Rays for all kinds of observations
along the horizon in bright day
light Bright pinpoint The periscope
Mirror can be viewed by compressed

If a Beam strikes his periscope
glass it would be deflected
Search & reveal his presence

Bomb - make it somewhat spiral
fine teeth - use an inclined board
teeth in the Direction
bomb - Hold bomb
Sure Recoil Device Mirror
or hand machine, Key drop at
on board chart, cap incline
& Collapsible over all the
Ingredients - Then would be
lighter & triangular Upon
propeller wheel

Photo plate may probably be made more sensitive by electric heat

Possibly a 300 to 500 telescope pipe with rotary mirror [illegible] if disc used as perscope [illegible] used.

Aeroplane propeller to go to limit of vision from tower Need gas discharge which on lighting or ignited Magnesium powder to ascertain Visibility of ships — also Calcium Carbide + Carbon to ignite at Throwing away of vision over wide horizon possibilities as suggested in Spanish Civil War —

Try the Tinsel Lacer telephone used for range for Midshipmen Intercommunication —

Ditto air compressor pipe system of drop tube Gauges — Central station Head telephone —

Wireless, write to Commander-in-Chief Communication as fast as can write

From ship to ship — Tube Communication phone Think they make porcelain lined tubes — ?

A good AI smoke producer is going to be handy —

Ditto a tracer for projectile — smoke —

Any bulkhead used in a turret should be in an Explosion box

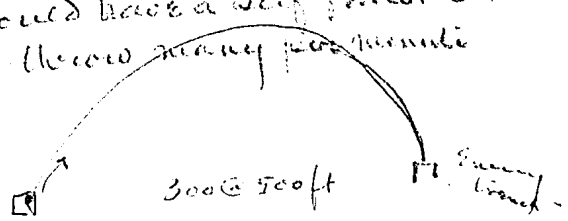
Why not correct the droop of 6" gun by a tricon plate — This would help expansion & prevention of cheating —

The lining of a gun after Boring should be mechanically scraped & then honed & rifled — I am not sure but that it should be hardened —

Try Experiments by pressure Gauge thru a tube scraped & unscraped hardened & not hardened — This will give a rough idea

The Ethonic force (sic) Hertz? of the dynamos on war ship may be a source of danger as a drop formed or a pole in wire rigging may give a spark — Try —

Burning bomb tube with
Oxide packets using gasoline —
Say 4 feet long keeping up
the pressure during Intake
Stroke probably Petroleum &
Naphtha or Pet Benzine better
or Kerosene — Beyond adjustable
piston used with Capped rod
Extending thru End of Cylinder
with Extension guide for bomb —
Use Compressed air to clear —
Could have a self starter on
a thrown away part of mechanism



The kind of Trajectory
should be readily measured
pockets + angle control deflection
+ Trajectory —

Right angle or communicating trenches
should have board or sheet iron
bottom with Shrapnel bullet Can + cans
to bring up men + return bucket Cans
go back with old shell — also bring
up ammunition + grub —
& Inserts good upon — probably
grooves in boards to guide

Motor trucks should be
designed to go over hills ploughed
fields, stumps butt away
fences + make good time + not
depend on roads at all —
going thru woods, a tree severing
Truck should cut away the
trees fall + remove leaving stumps
say 1½ or 2 ft + the steering
trucks should follow guiding
after these stumps —

Cantaccuzeny Hypocrite de la
chlorine would clear the air of
Chlorine if Every made has one on
large trucks ready — Kill it before reaches
trenches —

Tear producers can be taken care of by recollection Extremely Painful but over by sticking by sticking plaster.

If the Rock of Gibraltar is of any Value why is not the Navy sink) Monument at Sandy Hook

With a harpoon gun throw a lasso with 25 or more feet loop over a periscope with a quick pulley drawn section to tighten loop + draw to pull off periscope

to a whitehead torpedo appears the Mariner fires a hoop with various devices of diverting Explosive bomb to divert its course or explode it,

two arms with fine wire (looped) Cable Connecting a heavy iron plate under water, when Torpedo is screw work water to bring plate in its path to Explode it - say 25 ft from boat. This can be guarded against. When torpedo can reached

Run up from the fighting mast a pipe like mast to carry dully very light at 150 ft beyond top-sailles put a periscope for observation

At sea 50 or more miles out lay small cables with microphones strung along every 500 ft & resting on bottom, strg 600 to 1000 ft deep - 20 miles each way from end of a land cable to Gibraltar & Canaries 600 miles long will require 15 stations, No ship could pass without be known a number of whipps & positions (500 miles)

Think position of a ship by sound of propeller Could be triangulated & torpedo fired without a periscope -

Think Mines could be strung along Coast 50 miles or less out & controlled by Cables & fired by a submarine -

Can a gyroscope be made to guide a small balloon with Camera & blow out a certain distance by a time clock stop and start another gyro to bring it back.

Study up the Range finder & the glasses they use

Can a special small gun 2" be made to prove the range by making a hit giving an electric arc & momentary appearance of dense dazzling white smoke & forming rapidly. If the characteristics of this gun is accurately known the big gun should score hits from actual Experiments

Why not make a very small machine gun with a removable brass chamber into which from a coil lead wire is fed using 1/8" bullet. This is cut off from a coil smokeless powder is fed in & cut off. The record used to feed. When removable brass bush is worn, remove it use the grass from powder to compress & fire to cool the gun.

Alter the feed so more or less of the powder tape or cord is cut off according to the range.

Notebook Series -- Notebooks by Edison
Notebook, N-14-04-03.1

This notebook was used by Edison during April 1914 and was annotated at least once in 1916. An entry on the first page indicates that the work was done at Edison's laboratory at Fort Myers, Florida. The book consists primarily of 87 numbered entries entitled "Notes on cause of Low % of good disc output." The entries describe ingredients and processes involved in disc record manufacture, identify the potential sources of problems, discuss experiments done by Edison to improve record varnish, and suggest additional experiments to be performed. In entry 58, Edison noted that the problems resulted from variations in the thickness of the blanks and consequent differences in pressure on the transfers at different spots. Following entries 84 and 85 are several pages of notes on separating nickel flake and nickel hydrate recovered from old storage batteries and on a "New Scheme" for the battery. Following entry 86 is a list of eight "things to 1st receive attention" when Edison returned to New Jersey. Near the end of the book is a one-page summary of the results obtained by William W. Dinwiddie in his experiments on the expansion and contraction of Condensite veneer, along with the notation that the information was "Entered in 1916 Book 3." There are also some calculations regarding wages and general expenses. The notes indicate that Sherwood T. (Sam) Moore and Ludwig (Louis) Ott assisted Edison with the disc experiments. The front cover is labeled "Disc Records. Fort Myers. 1914." The pages are unnumbered. Approximately 60 pages have been used.

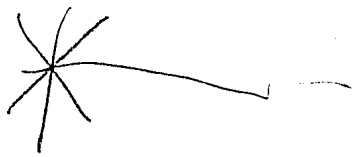
Ft Myers April 3 1914

Notes on cause of face % of grad due accipent

1 = Temperature of Blank is different from Transfer when assembled or one is been made longer than the other with Consequently more internal strain.

2 = Penta smoke or smudge may act as a surface Lubricator + do good, and when Penta is carried to a long in Chlorination smudging Malapping may be absent or reduced, smudge may allow slips. When we didnt use Penta % very Low, cracks but the moment used Penta % went way up, but smudge was great

Probably due to Ferro Chloride in Penta Cause of smudge or Easy leaving plate



3 = Penta chlorination carried too far, too acid, also oxidizes, If oxidized no longer soluable in water, I remember however when we were using white distilled penta & was getting high % Suddenly % of transfer went bad without any change in distilled Penta.

4 = Look out for rapid Oxidation of Penta I have noticed Penta being thrown out of Varnish on plates while Evaporating This would tend to segregate Penta, The precipitated Penta shows especially when our strikes Varnish & waves are going on —

5 Too much water gets in The Various materials used for making Varnish, Alcohol Wood powder, Resin, 6/4 —

6 = % formaldehayde in Dryer Escapes + makes lower grade of Resin, hence large part of 6/4 added as naturalized —

7 = Edge of blank in Transfer press is exposed to air + chills quicker + also never reaches platen Temperature — Center always hotter

8 Some men open water Exit wider than others also Water entrance End cools quicker than Exit end, gives unequal contraction Some steam valves don't shut tight, steam leaks into cooling water, hence blanks not chilled so quick —

9= Air draughts one day different from other days + temperatures different Copper leading in pipes condenses steam + get lower steam pressure + temperature. by air drafts

13= Ovens cool down from 225° quicker at times + produce strains Cooling with cloth Covered trucks not long Enough + go To press strained

14 Wiping rags in Print room greasy - permits slip on smooth Edge of record when not welded at spots + this start Crack -

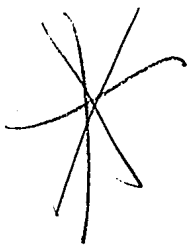
15- Bad Prints not Enough free Phenol + transfer gets too hard making Varnish too hard to flow + fill Wants more free Phenol, is cause bad prints

16 = Penta, oxidizes in mixing Board

17 = Free HCl left in Pentacyacetate on Calyx-Eosin + makes harder Varnish so can't flow in printing Must soften Varnish to get free —

18 German D plates, have at different times a smudge or residue — absent on other days. Thus affects transfer — this smudge or residium may have become offset on Sesame —

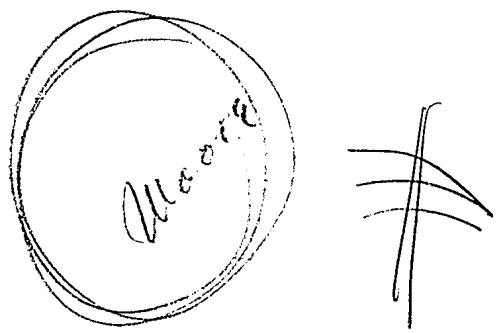
19 To much alcohol used on plates — one condition of Atmosphere + draughts nearly all goes away — other days but fickle goes off



20 = Without Penta, or Para we get very low % 40 to 50
With Penta some days we get high % next day low %
Effectiveness of Penta depends on some change in process -

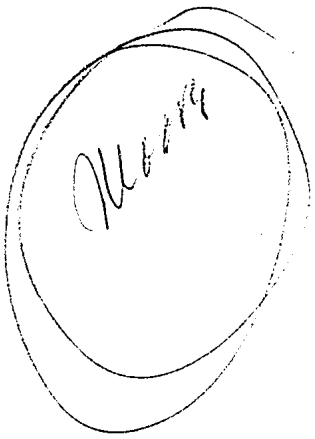
21 - Once we made lot of Varnish with only 2% Para no Penta & got 100% Transfer & 100% Print never got anywhere near it again ~~+ no Penta~~

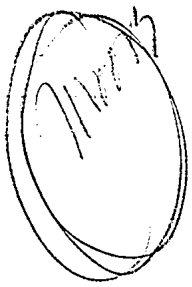
22 Once we made lot Varnish using only Para 3% it dried & cured solid in 2 hours in bottle Then reduced it To 2% & this was used in No 21 above Methaens old Crude Para Now cant get it to dry within 24 hours why



23 Very few prints show conspicuous Cracks in Print room - in room next to print room shows 2 or 3 times Cracks then They go to Inspection Dept. + they find 25 @ 30% more This shows that the Veneer is strained + our drawing + handling Causes Cracks — We should put holders in boxes + immediately Records are removed from moulds should be put on holders in boxes + lid put on + held 24 hours before machining to allow strain annealing —

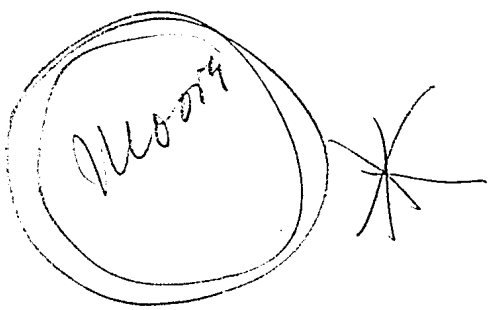
24 Grease from hands get on blanks on transfer and on print, the transfer - No weld on transfer. — On transfer no weld on pat + get Crack on print, no grip on edge at pat + we get cracks





25- If varnish cracks after taking out of Oven by a breath of air + taken gradually within a few degrees of the Atmospheric temp - or if out + OK + then put in a draft or little Cool Air than room Temp + they Sometimes Crack Why Should not Prints Crack if Exposed to air after coming out of press Why Should they be given time to anneal.

26 After Prints are taken from the Mould they are under great strain of those which are not cracked many will Crack depending on position they are placed + air draft Should be given a chance to anneal.



27- Possibly we should let off the pressure in both Transfer + Print very slowly after Cool, taking 2 or 3 minutes, to no pressure on gauge then rapidly after Heat. The sudden release of pressure may make a snap, a crack, a thing Can be done gradually that will snap if done suddenly —
Also possibly pressure let down with heat as it goes down, especially after Vacuum is cut

28- Think we do not want oven press phenol in Vacuum Pockets of proper quantity of blank surface will be soft + flow easy + stop good prints + will wear OK - any great excess will cause demand to cut

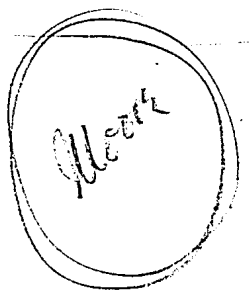
29- Think that screen is very variable as to free phenol & some way of reasonably testing the above proper addition should be devised -

30 = The action of 6/4 with proper amount of free phenol in Varnish is to harden the resin very hard & to turn the free phenol into a soft tough Condensate Tough at Low Temperatures If not enough free phenol Veneer is to brittle & board not plastic enough for our processes If too much only defect there is that Resin will not be hard Enough & free phenol too soft & these give high plasticity & stop board pores but Decomposed will cut & it will be softened by alcohol

31= Our End March to April probably due To Variable Phenol, when Formaldehyde Escapes we probably get More plastic Varnish if not Controled properly by Haffman= if made without loss of its probably too hard & we get poor results.

32 The Occasion Para fors Varnish quicker at one time Much quicker to Love to Variation of free Phenol a low free Phenol Content. Varnish will be thicker in say 3 hours than it would if Excess free Phenol Cure —

33 - Blanks vary in amount they will diminish in thickness in Transfer & Print process from bad Mixing of Varnish or poor baking in Oven they being in different positions



34- Perhaps we should put some free phenol in wood pulp Varnish — Possibly Paula + Pana to ~~toughen~~ it + make it semi plastic

35- My chemical Room expands with 1½" plates with great Excess of phenol show that a corresponding Excess of phenol Can be used in fact no limit until the reacts wears

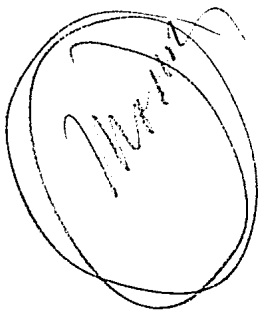
36= Enclosed at Myers Hall Condensate Made almost from phenol & 6/4 is very little affected by KOH, Cold The smaller % of Cond 2% dissolved out & precipitated by HCl is like Spruce gum for Chewing — Better try it with hot 25% KOH, if good residue Could use as a filler for battery hard rubber

37 It is possible we have too much free phenol + it crystalizes + makes it contract & harply around 110 deg

38 Perhaps if we need more free Phenol that when we have the right amount in Varnish it distills off in oven by going to high or keeping at too long at high temp +

39 We should try an excess of Phenol + then run at lower temp in oven to prevent distilling off.

40 - Perhaps with our present uncertain amount of free Phenol it would be safer to come down 10% on 6/4 or until it dont Cut - then cheaper



41 - We should test our plates Cocquelaine for % + Impurities +

42 = Perhaps our Screens are getting thin from using through of too great velocity being Then there is no margin of flow to take up irregularities of Blank & make good prints.

43 - I notice colour draught is strong over Varnish plates while Etching that the top is very hard + brittle + Callous Comparatively much softer, possibly the metal draught in ovens is not good -

44 - If we don't grind the Blank powder fine the Blank will be denser + thinner + by time it reaches print press it won't gross + permit a fill - the finer the more difficult it is to hold on it.

It has a spring back to it.

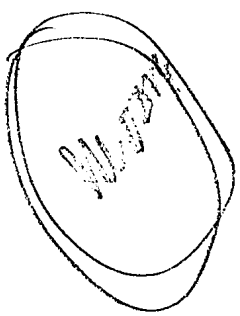
45 & In this connection to get a greater spring back to slop poor prints one might try 4½ to 1 instead of 4 to 1 of Furmoka wood fibre. This will be far more springy & of ground fine, stick more.

46 Today took
10 grams dusky Phenol
700 Mlg 6/4
1400 Mlg Modernday soft Penta
not washed.

Put in dish in Copper oven & over a period of 7 hours got 1 to 220 — Result was

Original weight	12100 Mlg
Residue left	5700 "
Loss	6.400

It was solid black brittle resin solid but softened heat of hand & at low temp was very thick



Tar like dough, sticky & tenacious
I think the free phenol in
Reg Var gives this —
It might be a good idea To use
phenol free Resin in Varnish
& then make a lot of about
Tar, add 5 To 10% To Varnish
it certainly would lower
the softening point & prevent
Records Cracking & give a
free flow for printing —
By liquifying the 6/# in
making the Tar, Could get any
result required —

1/7 = Have to a good schemic.
print record, keep pressure
on, the blank & Veneer will
be cold & not cracked, now
turn water off - put on steam
for few seconds still Veneer
heated up slightly — Cut
steam off & remove
pressure & take out mould.
The Veneer will be expanded
more than blank & can't crack

48 – We should get up boards both ends & put a test Varnish plate in each & Vicat needle to get the softening point – perhaps immersed in water & that heated in mud & remove every ½ hour a plate with glass & diamond Reader wear test then the Varnish that softens nearer 80 Fahr The less Cracking or poor points –

49 Varnish sent to buyers without G/y – acts different
Should have a Sample, and to random Varnish & mix & put in Screw bottles G/y & Kept & When Varnished G/y put in & mixed –

50 - Weather Report not to keep plates 24 hours before working

51 - Perhaps Chloride of Phenylene Diamine, Wood Alc & Bette Naph Base, or Acetate

52 Recently Coca mix. 10% or so Raw wood Alc to time with Hack powder for 6 hours & Plates get Electrolyzed into Lampblacks

53 - New scheme - melt wax thinly Dip Blank not Cool Varnish over surface of Plate in strong Alcoholic 6/4 - Para Phenol Solution with Formic or Hydrochloric dry & Print Chromate Change & develop to condense the Silver face Layer

54 = Treat the Varnishing Experiment
Lott is doing —

55 It may be use paint too high & too
long or high Varnish not
tacky medium so that in transfering
Paper not plastic enough & also
not enough smudge to render run
or quick surface that will free
the transfer from plate, old
Paints that smudged always
Come free

56 – etc. of what manufactures
substances from keeping of the
may be left on plate – that
makes them come free & this
film stays on transfer block
& helps in printing —

57 – Para once condemned Varnish
in 2 known Evidently
some impurity died it
What was the impurity —

58= I think we have the trouble -
It is this — The blanks vary in
Caliper, several thousandths
on one edge as against
the other, The Top & bottom
of press is flat if it happens
that more thin edges of blank
occur on the right or near
to each other, the pressure
in bracketing arm are very
different. In other words
these variations in thickness
produce unequal pressure on
one side of blank, & there
by defect multiplied by
using 12 at once
Our thing is, the press must
as everything has pointed
that way -
EVEN if Caliper of all blanks
were EVEN this theorem
argues that when pressure
was on they moved to
EVEN — as in Mfg blanks it
impossible apparently to
make a blank of EVEN density

59 - To get around this thing - is going to be different ft. We can carry on + please. The Thick side 2 edge is moved North + next one South next East. Next West + so on + the 12

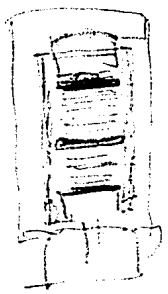
(1) (2) (3) (4) -

Nearly Every - Each blank thing occupied by a quick connect with rod at Thick edge, marked by white spot on edge -

The only thing that interferes is the pressure density which is not chosen by Cadapac.

60 = A false plate + possibly one platten removed - Top plate loose with a bolt put to get center pressure platens to lift + accommodate themselves to variable thickness of the 12 Molds + Platens Combined -

61 = Possibly Can get rid of Mounds & Patterns — Then



Assemble 50 blanks with plates of Varnish each side pile them on Top each other. Then another 50 — put both in a Tube — Heat by gas & when temp is 350 put on pressure 15 min Keep Temp Constant, Then remove & cool slowly — With Thick rubber Collar pressure & Swivel ball - gets Even pressure

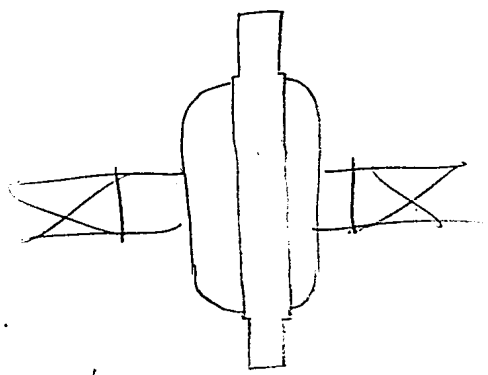
Possibly steam jacket vented by vent, steam evaporated or just Hot Air —

62 - Callipers by a round drawing showing high and low work of blanks then place Hammer Mandrel press High end, X S E & West, Mandrel up press & examine spelling tab many high ends on one side of press -

63 - Lay blank on hot plate use hot conical rollers under great pressure, roll & bank out to same thickness -

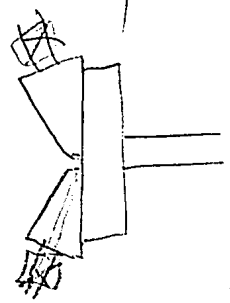
64 Grind one face against Emery wheel or grinder true up by Diamonds then clamp in chuck against a face plate Chuck claws or taper ring - face with Carborundum wheel or turn with a diamond

65 =



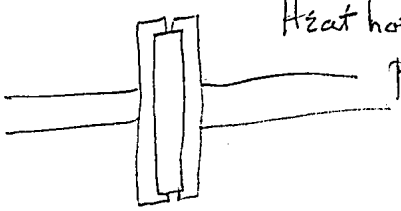
face edge + sides in 1/4 inch
both sides or one side to get
a true bearing to face by —
+ turn both sides with diamond

66 —



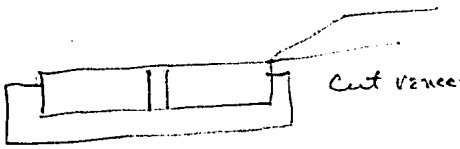
Conical rollers
true up Disc

67 =



Heat hot, put on bag pressure + release in op direction

68 -

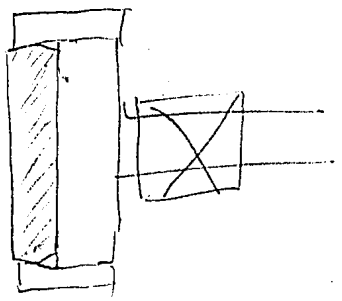


cut veneer off to true blank —

69 = Put in Top + Bottom of press
One each top + bottom of defects
to permit alignment of platten
with uneven blanks

70 - Lift ram Ball joint in Top + Bottom of press to permit alignment.

71 =



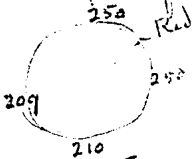
Blank (bevelled) two ways — use chuck + tighten by the Taper and Edge, face width diameter) + then turn off face other side — 400 Rev min — grooves 2 Cone belt Countershaft

72 — Press a cake 10", 6 long Chuck + saw off disc blanks with diamond saw Could use a steam operated Cylinder for Mould.

73 Use square mould + pack Powder same as we pack Iron packets, then Cut or punch out discs

74= Print turn heat off, wait ½ min turn mould ½ way around + heat + press, then cool -

75 - Calipers blanks, put Red mark on edge of center of high side,



closed 66 N S E + West,

76= NEW = there is a drag in jacking to keep up the pressure in cooling. The more the pressure go down from malleation, then bring it back, sometimes it goes away down before they notice it -

Now suppose 3 sides had most of the pressure + on 1/4 had light pressure. The fall on cooling

might not be enough to loosen the grip on the heavy pressure joint but on the 1/4 of area relieve pressure to light the grip is small & it will not stop veneer from contracting hence Cracking. The only safe way is to not only stop these loss of grip by not losing pressure but would be good to actually increase it -
This probably Explains why some men get better % than others. Even smaller of blanks would stop it,

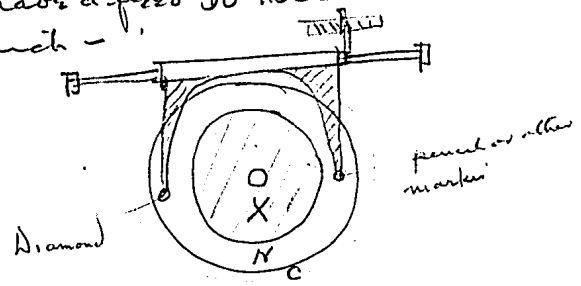
44 = I think that if pressures of a defendee is say 1000 lbs that the moment we over approximate above slightest tendency to face that it would be well to group events 1100 lbs to be safe and this would prevent loss of grip on contact surface

78 24 Veneers 15/1000 Each
Can deform down To 8/1000
drop To 22/1000 —

If we have 24 Veneers in press
15/1000 Thick This is Total of 360/1000
of Veneer

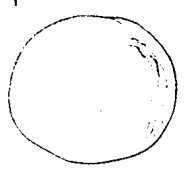
If deformation is necessary to Correct
wherein Calliper of blanks 8/1000
on one edge 22/1000 on the other
it gives a deformation to Each blank
of 28/1000, or 336/1000 to the
12 blanks —
This requires thick centerline of top
& bottom to allow alignment of
platens —
If Blanks more than 22/1000
thicker at one place than the
other is bad 22/1000 is the limit
and it should not be more
than 11 To 12/1000 —

79 To test blanks for thick + thin edges - rotate blank - have a feed 50 threads or less to inch -



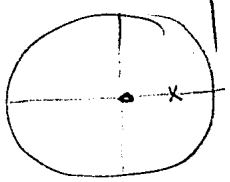
X Top plate
C platter
N Record - held down flat,

When low side passes under Diamond the pencil comes down + marks



The idea can be worked up -

80= In loading use thin



removable metal Separator partition
Weigh 4 portions of wood fibre put
on in each - Remove X - then
whole will be even to start with.

81 In embossing the ~~tits~~ on working
mould connect the tits together
by a 002 to 004 high 10/100 wide.-
Emboss - On printing this will
hold the veneer while contracting
+ in final Edging come off +
Dez of bosses have not been changed

82= Cracks never start on second
part, but only on smooth,
its because Veneer is not held
on Cooling - No 81 should fix
this
To stop it at transfer, make a
Chaser with 1/8 wide of ring
teeth 150 threads & chase the
Varnish plates clear to edge
this will hold it in pieces
When Cooling on printing
it will not show -
We could chase smooth part of
record also, & Miller could
touch all new ones -
On transfer plates as they are
irregular can use an advance -
Back Make on recording Machine
see who can manipulate for ring for
ring at Edge & use thumb if foreign

83 – Possibly we want to run Varnish plates up gradually as possible to reach the rubbery state, then there is no danger of segregation of Pearl, Paint or Gold. Then can go all over Think this the trick to get even Contraction & reflection —

84 = Making Veneers —
Used small granules of following in Reg Varnish ~~—~~ poured from Reg Var a small quantity into a separate dish added the Chemical & stirred it then poured on one of the little plates —
Let all stand in air over night & then gradually heat up to 185 —
After being all night in none more fired

Used Co SO4
Fe Tannate
Fe Picrinitric
Cu Nitroprusside
Cu Oxalate
Fe Sulfocarbolate
K Sulphite
Ba Sulphide
Aluminum Chloride
Antimony Chloride
Cu Cy
Sulphide Zn
Cu Chloride –

Practically all except Rubbery
around 145° Fahr

Sb Cl very rubbery
Al Cl next "
If pencil pressed in either no hole
of deformation left, not true of all
the others they come back slowly
+ leave a slight mark,

Sb Cl is the most abnormal

of the lot, AlCl made lots bubbles - SbCl acts + apparently precipitates, turns from black to brown surface not flat or shiny seems thinner than others, there are internal bubbles which cause up + down a wobbled surface of little hills -
All others shiny - Req the most SbCl least AlCl next,

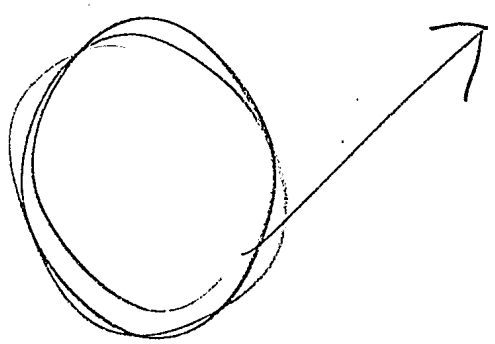
At 160° SbCl still very rubbery all the others very stiff rubbery + all about the same - AlCl probably a shade harder.

185° SbCl still abnormal
Still Rubbery
Req + CuCy blistered.
Cu Nitroprusside all blisters
Ba Sulfide next hardest to AlCl.
Req + CuCy one other + no bubbles
K Sulfite Cold Cuts Tough, head holes
Separate from plate hard
BaS cuts little tough Separates OK

AlCl Whitens plate, Cuts semi Tough
Comes off hard –
CuCy seems tough & powder good
Zn S " "
CuCl - brittle dont seperate good
Fe Piconitric brittle, sepo bad
Fe Jaunate " " fair
CoSoy Brittle sepo good
Cu Oxal " " only fair
Fe Sulfocarbolate Semi tough sepo fair
11 Reg brittle sepo good
Ce Nitropruside Semi tough Cant sep bubbles
Antimony Chl Trichl - Tough like
leather, flexible like Letther Cold
Unmarked on celluloid Easy
fold it, KOH dissolving also at
Water no effect.

While SbCl3 if coppers than celluloid
it Cant be scratched by fingers
nail - and with a Knife Cant
scratches Reg bad dont
scratch SbCl. its tough –
dont chip out when Knife pressed

Possibly anhydrous $LiCl$ or $CaCl_2$ would not



over it, I used altogether too much $SbCl_3$ It's probably probably lengthens it,

If not $SbCl_3$ is precipitated by water, giving white ~~ppt~~ ppt "Algaroth" =

$SbCl_3$ dissolves in alcohol there is a precip white from water in alcohol I follows the precip off get clear & then added water & white precip came down +

Evidently when I added the $SbCl_3$ to Reag Ves it took out the water + formed a precipitate in the Vessels The white pp Turned at from black to brown Comes off plate hard

Something in $SbCl_3$ Juice —

S Battery -

Think Hypo would do as good for deoxidizing, but expensive.
Clean after operation with 1% H_2SO_4 or perhaps HCl if burnished in bbl my Experiments always Clean off flake nicer bright Nickel Coat will Clean with HCl for cleaning very little of H_2O_2 operation but more to load H_2SO_4 used

Can use the 1% acid just enough to make mix little thinner than a mush

Can float most flake off by old way of letting water up from Carbonic box for 1 after the C Sug flake Coat be removed out the H_2O_2 no longer OK for reuse —

Next page

85 = Further Experts show that $SbCl_3$ dont toughen What it does do is to delay the final hardening, by running all up to 18d 19d after stripping from plate, they were all bright

Ferric Chloride was the only one of last lot that was remarkable it Came off the dush perfect not sticking as all others did —

Mixed pinch of each in Beg

Sb S.
Hg S
Cu S
Sn Cl
Bi Salycilate
Ferric Cl
Pb Hypersulphide
Sn Bi Sulfid
4 Strengths of $SbCl_3$
Beg -

I notice when I pour the varnish

Battery -

Contrary what texts are made of Hoff @ operated meant be looked in a cyanine to see if it to green or not,

Perhaps Hoffman's white ash to advantage out something forming a double salt,

Perhaps other salts which tend to form double salts will take of further things will after Hoffman has been washed out -

Next page

on the little plates, that the SbCl3 shrunk very much in thickness, Thinner seems on 1/2 thickness of all the others

at 135, all were condemned the rubbery state except SbCl3 changed very very weak SbCl was slightly rubbery - the other 3 SbCl3 not touched

160 Tested all condemned rubbery Except Strongest SbCl3

[illegible] after having at [illegible] all hard - Ferric Chl has dull appearance -

Ether taken out has had most bubbles, + strong SbCl3 not.

Put them all back a piece 1 to 2 hours around 190 To 200 - all reached hard SO3 Condensate all hard - + about the same in properties -

From these experiments it is

Battery = New Scheme

To make our reag $Ni(OH)_2$ proper use say 1 to 3% H_2SO_4 acid — dry the $Ni(OH)_2$ + then just neutralise it with the acid solution dampen it so to speak then practically all the acid will go in the pores & left all day then it can be washed out leaving the $Ni(OH)_2$ proper, any degree of porosity can be determined test it. ——

I noticed when I boiled on Nickel Fe from old cell by HCl + by H_2SO_4 — + HCl + a little HNO_3 latter gave no black film of coal stuff — whereas H_2SO_4 gave some —

Easy to see that the Time & temperature as VERY IMPORTANT

to get a tough veneer don't go above 200 & don't heat to long at high temp, & 4 or 5 hours & perhaps longer is the time that is required for 1st stage in Rubbery condensation around 140 for 1 or 1½ hours 2nd stage in hardening & drying off alcohol etc, if not stopped here, veneer is tough in 3rd stage to heat & bottle 190 @ 200 for say 1 hour

When get a new change. Schedule to get tougher finish & stop & fiddle at 160 stage,

I made some very tough & Transparent stuff from using an indifferent of formaldehyde in phenol then dissolved in water 24 hours — This ought to be a good solution to Varnish

86 = I feel sure we can make 2nd prints by using condensite Veneers on metal + bring to rubbery state + just before pour on mixed with removable rim - Then print by using hot water, don't think it will need more than 150° or less -

Could also use 1/4 g face mounted on halide sheet, flow a condensite on g face remove to halide, print, remove + plate,

I think the resin condensite veneer will take negative OK if temp has been kept low

When I arrive Home These are things to 1st Receive attention

1st Make experts old Cell mixer operated by 6 def Chemicals Wash + treat with H_2SO_4 – Acetic HCl HNO_3 + Aqua Regia Ni crushed + superheated screen – test in small Tubes Sep flake by Chemical Ox + Reduction

2nd Reach bat tray + make mechanical tools

3rd Hand men making Even Caliper blanks

4 Extra flake Cyn Varnish + Cry need Oven Reach tube to get safer Temp – 190°

5 Floco Condenser with ring of glass or porcelain or metal held in Metal ring – Use ↑ just beyond Rubbery range Use 150° To prevent

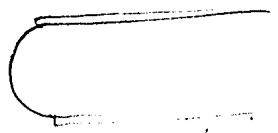
1/10000 thousandth
inspection —

It looks as if all blanks that will not separate can be either double turned or separated & or double transferred, that has cracks could not double transfer but can be turned & retransferred on

Notice one transfer that has squeezed out round -



Now this shows bad mixing too much in Hammermill fibre -

Result of Experts with Varnish
Reg + Reg with some Viscous
Semi Condensate in — for use in
submarine work —

We can use 1/4" glass, or turned
up porcelain supported in a sheet
mould — Flow the glass, porcelain
or metal with a ring around it
like old submarine Cable Insulate
Remove ring after drying — Then
put it in Water Jacket Oven
~~XX~~ & bring up to 145° @ 160°
for 2 or 4 hours or less — Then
Mount in supporting Holder &
Print at about 120 to 135, Coat it,
Then Graphite it & Electroplate
by Specially filtered Varnish
+ putting in | clean Oven, filtered
air draft Then a no heat for
a while, We should be able to

discard the d—d Calculated

Think the Semi Condensate Vaseline like muck or a muck not acted on by G/F will be best to help grind filling — not sure, try —

Reg & Reg with Semi Condensate muck

2 hours at	117° Fahr
1	120°
½	142°
½	160 —

Too soft yet Can't strip from plate but the one with Condensate muck Comes off

Sections of both when cold are flexible like Leather, The muck one much more than without muck

When Very cold Reg Cracks showing that at 160° would answer for submarine — But the mucked one dont crack — but remains flexible + Too soft for submarine

After ½ hour Reg Can be stripped some — Top fairly hard, underneath rather Leathery

½ hour more 178° Fahr Reg seems hard enough for aircraft — sticks hard to plate, Can't pry off but Mucked Var comes off — but hard,

After getting Cooler Reg comes off best hard,

I made the copy Semi Condensate by Condensing Phenol with Very small proportion of formaldehyde, its like Vaseline but quite not so thin —

There is a big difference between mucked Varnish & Reg

Believe we can work easy Var on Ovens at 180° Fahr

About 160° is OK for submersion mucked Var - Very flexible, Reg OK -

Keeping it at 180° 3 or 4 hours more it runs unnecessarily hard

180° Fahr Mucked stuff taken impression of 10 ℄ piece OK
& looks as if mucked stuff too
Graphite OK -
Only one defect & that is top of Under Very much harder than the bottom,

142° Fahr Veneer takes graphite OK

Notebook Series -- Notebooks by Edison
Notebook, N-14-04-26

This notebook contains dated entries from April and May 1914, but it may have continued to be used as late as July. The entries, which are all by Edison, pertain to experiments aimed at the rejuvenation or "regeneration" of used storage battery components. The entries toward the beginning of the book deal mainly with the nickel flake and nickel hydrate mix from old positive electrode "tubes." Included are lists of chemical compounds, along with results of tests performed on cells constructed with various regenerated tubes. The entries in the middle of the book deal with the iron from old negative electrode "pockets." There is also one page of crossed-out notes on the manufacture of disc records. The battery experiments bear sequential numbers, 125-141 and 142E-240E. Experiments 129-184E involve various chemical compounds that were prepared by Ludwig (Louis) Ott and used to treat old nickel. These chemicals are described in N-13-10-05. Some of the cells produced in experiments 142E-240E were apparently transferred to the Edison Storage Battery Co. at Silver Lake for continued testing. Their subsequent performance is tabulated in N-14-12-14.1, and the sequence of experiments is continued in N-14-12-03. Inserted into the book are two reports from July 9, 1914. One, addressed to Edison by John V. Miller at the Edison Chemical Works, reports on experimental pockets prepared for experiments 240E and 250E-252E. The other, addressed to Robert Bachman, describes several experimental pockets prepared for Edison. The front cover is labeled "Somewhat Important" and "Regenerate No One." The pages are unnumbered. Approximately 120 pages have been used.

April 26 1914

Regeneration of Nickel flake from 4 yr old cells that have gone low in Capacity

I note that flake & green from use of glycerine & KOH as desulphurizing agent, on treatment with acid when glyc & KOH are washed out act different according to acid used –

2% HNO_3 gives clear solution only little green color

2% H_2SO_4 ditto

2% HCl gives yellow green Milky liquid & does not get clear decolors Ni but on filtering. Muddy yellowish Colloid continues to run thru, apparently no let up, even after acid gone

The muddy deposit treated with HNO_3 becomes green & clear showing lead is mostly metal. The clear acid precip by ammonia shows a small amount of white yellow iron — precipitate Fe_2O_3 —

This is true with 1% HCl & 2% HNO_3 — but not bad like 2% HCl

Evidently HCl has some action that the other acids haven't.

The only one that is perfectly clear is H_2SO_4 —

I am separating 4 batches of 4 yr old mix from tubes — These have been put in 5% 10% 15% & 20% glycerine & water & 3% KOH or NaOH in each

5% didn't disintegrate at all -
10 had more disintegrated
15% About half
20% all were disintegrated
Kept them in flasks on hot plate with 1/8" asbestos between flask & Hot plate. They used great deal of Graphite

Lots Nos

129 - Considerable pieces not broken up

132 Nearly all broken up

130 Nearly all broken up

131 - 9 pieces

136 - quite amount of calcite
& ammonium

Thus - K formate &
it may take out
aluminia ~~etc~~.

I now put 2% HNO_3 on
L.Ott #

136 NH_4 powder considerable calcite
126
127
134
135
125
128

They all have been well
washed - 10 or 15 fresh
waters — put aside
— Mix of Na & flake —

No colloids that run through filter
in any of above, take #8 in
glycerine ROH. mix -

All above about same
degree of granulation

The least green is from 128 —

of the glycerine Series —
only HCl, shows ferric
Iron — HNO_3 H_2SO_4 &
1% HCl 2% NO_3 white flocculent
precipitate alumina —

Apparently to the HNO_3 that
takes out the Alumina
H_2SO_4 takes out some

But HCl + HNO_3 apparently don't
take out ferric only the
white pp,

It takes 3 or 4 hours for
the Alumina to come down

None of the precipitates
were green except glycerine series

Salicylates can be washed free of Na or K Salicylate — approximately —

$HNO_3 + H_2SO_4$ + glycerine are the best to work no emulsoids

of the solution (acid) decanted off from precipitate Number Except glycerine series —

127 & 134 ~~are~~ have the most but it will require longer time to be sure —

---

129 - acid oil followed off & H_2O very large White Al sic precip - has a reddish tinge showing ferric —

I have sent
129 130 131 & 132 separated by me

After drying I screened green & flake
thru 20 mesh —

Had to crumble flake a
little to get 25% that stayed
on 20 mesh —

Green left only little flake in
Grave Receptacles to Broken
Ends to be made as follows

2 tubes old Mi old flake
2 " New Mi "
2 " old Mi new flake

134 & 135
give big yield of
grain
100 grm
whereas
126 & 127
give very small
yield 1/-
probably lost in
the sieving.
50 grm

Note scarcely any Alumina in 135 —

Lots of broken ends of tubes & Caps in all —

134 - not well disintegrated, hard to separate flake from matrix connect in goes over each flake — It will be difficult Comely to separate —

135 - disintegrated v. easily well — Hard coach in out of flake Lots Cortical on attrition, Final rem. Matrix fiber —

136 = family disintegrated after acid treatment flake yellowish — but only some flakes —

I think most white precip
Supposed "Cl" comes out

128

I note that 20% sol of Chlammonia
with tube pieces in dewaves

Made 500 gms old Tube Mix in
15% glycerin 3% Kerr or Mason -
got very green - washed
flake away - washed
green weed - dried & put
about oz in different
acids 3% Dil, only put
Enough acid in to cover &
Cover 1/8 to 1/4" deep -
left all night -
In morning only one
that showed abnormal

Was acetic + Phosphoric
Phosphoric + Oxalic
Oxalic + Boric
Boric + Chromic
Chromic + Citric
Citric + Tartaric
Tartaric + Acetic

Was acetic — Citric Tartaric Acetic
Phosphoric are green Oxalic Boric Chromic
~~green~~ + on blackening + cools
~~green, but~~ acetic black
from black colour till
precipn — Liquid filtered
a green & black colour
left on paper — filtered
clear — all the
others filtered fast +
normal —

Soak out acids from green

Test like Example from Phosphoric
acetic and Citric gives large
white precip with Nitrate
acetic also some —

Ni green from 5.6 left in
glycerin 3% acetic —

Then to the green
Treated about 1/2 gram to the oz with
3% Phosphoric
" Acetic
" Boric
" Tartaric
" Citric
" phenol
Oxalic

Put in the 3% sol on Ni just enough
To Cover it for 1/8 hours in 3" beakers
Drank, left it all night & boiled
off — phenol no pp both chromium
or KOH, none with Tartaric
Boric oxalate — phosphoric
was green — Acetate left
Oxalate white — Acetic
phenol green very white
precip very little also it
Colloided acetic through the
See 2 pages ahead

Lowes off. use 100 grams
of Fe from old packets,-
Break up to 1/4 inch to 1/8
& soak in acc Manufacturers
your packet 24 in. soak
48 hours wash free dry
in acc & put in Corked Bottle

From Expts 142 To 148 – 148
shows that old ppt soon evaporated
to dry & ~~gritten~~ To phosphates
Aluminate, Oxalate (some
or Ferrates,

There is very little Iron in
ppt so Ferrate is impossible
Aluminate + phosphate
is probably the trouble,
with Ferrate Oxalate
or a Silicate,

The thing ~~that~~ that was in view
of 148 is To investigate subject
of phosphoric acid determination
has taken place

I notice lot of Irons from old packets put in various cards Some are trade, others just as strong as Test -

The - Most White process yarns Old type Nakol to Token next by [illegible] Corbin & Na formula

But the test in Gallery shows 925 NAH for cocoa & 910 NAH for phosphate — formula may be taken from cocoa Try it —

Phosphoric, to a big Phosphorescence — pleasant Nakol Makes Mich/Oil/2 most

Why ? ?

All Irons —

All on 230 Run Ordinary
Monday washed, washed 4
times, Total time 98 hours
before put out to dry —

All the old Irons
Couldnt load 5 grams
used 7 grams in
pocket —

10% Head of 12 mixed
used with all
149 to 172
All pockets checked
by tech maintain

Old Fe 4 yr.

149 E 4 yr cell Iron — 5 gram pocket, iron
3% Tartaric — No 149 E ground thru 60 mesh
Miller adds 10% new iron thru 80 mesh

9 now soak in Conc CoCl after rinsing from Dwells See book 2

Much colloid, filtering very slow on account of colloid running thru filter — Acetic alone has this feature, phenol a little. Phenol in alcohol more than phenol in water — all these are test must be some significance in it, =

Washed with Distd Alcohol all comes thru no color —

Old Ni 4 yr cell

Mr. T. A. Edison,
Edison Laboratory,
Orange, N. J.

Dear Mr. Edison;-

Report on Loading Tests of Iron Mixes
Made from Ferrous Ammonium Sulphate.

Your experiment numbers- 249 E
250 E
251 E
252 E

Tests made with Machine #704 - Factory Loading Dept.
" " by W. Archer, Storms, & writer, July 8, 1914.

Alterations to machine - Hopper supplied with two partitions to make small hopper, so that the small samples could be loaded into two pockets at a time. Arranged in middle of machine.

Samples considerably too small to allow full number of pockets to be loaded at once, and also too small to make much adjustment to reduce loading weight.

In each case, two or four pockets were loaded before the test pockets were loaded.

Following are the results;-

(Cont.)

[ITEM(S) FOUND IN BOOK]

GENERAL SUMMARY

Experiment	Dumps	Loading Weight.

"	13	8.150
Feeding O.K.		

This is the same iron as the others but not pressed.

Details of these experiments are as follows;-

(Cont.)

[ITEM(S) FOUND IN BOOK]

Iron was pressed in 10" Die mobile

Experiment 252 E- Moisture 5% 21 KOH

Pressed 2000 lbs.

Special iron #1945.

Thru 10 mesh; fines in.

Setting of cams, etc., same as for regular iron mix.

Loaded two pockets as preliminary;-

" four test pockets;-

#1 -	19 dumps,	Ld.Wt.	8.93 grams
#2 -	20 " ,		8.79
#3 -	20 " ,		8.98
#4 -	20 " ,		8.995

Feeding O.K.

Experiment 249 E- Moisture 2% of 5% KOH

Pressed 2000 lbs.

Special iron #1945.

Thru 10 mesh, fines in.

2 pockets	- General test	- Dumps	15-16		
2 "	- " "	- "	15-15		
#5 "	For Special "	- "	14	Ld.Wt.	8.66 gms.
#6 "	" " "	- "	14		8.87 " .

#7 "	For Special "	- "	16-		8.86 " .
#8 "	" " "	- "	16		8.93 " .
2 "	- General "	- "	16-17		
2 "	- " "	- "	18-19		

Last four pockets high in dumps as small amount of iron was in hopper. Feeding O=K.

[ITEM(S) FOUND IN BOOK]

Experiment 250 E- Moisture 2% H_2O.

Pressed 2000 lbs.

Special iron #1945.

Thru 10 mesh; fines in.

2 pockets - General Test - Dumps 13-14 Ld.Wt. 8.98 gms.

Increased stroke of cam to lessen Loading Weight.

2 pockets - General Test - Dumps 13-15 Ld.Wt. 8.97 gms.

Increased stroke of cam to the limit.

2 pockets - General Test - Dumps 13-13 Ld.Wt. 8.80 gms.

#11 " For Special " - " 13 8.69 "

#12 " " " " - " 13 8.85 "

Feeding O.K.

Experiment 251 E- Moisture 5% saturated LiOH

Pressed 2000 lbs.

Special iron #1945.

Thru 10 mesh; fines in.

Same setting of machine as last test in Exper. #250-E.

2 pockets - General Test - Dumps 14-15 Ld.Wt. 8.575 gms.

2 " - " " - " 13-13 8.495 "

#13 " For Special " - " 15 8.670 "

#14 " " " " - " 15 8.420 "

#15 " " " " - " 15 8.560 "

#16 " " " " - " 15 8.460 "

Feeding O.K.

In all cases the feeding seemed to be O.K. as far as could be judged with the small samples. No clogging whatever.

After completing the above tests, made a test with a small sample of Iron Mix #1945. Same iron as in above tests, but

[ITEM(S) FOUND IN BOOK]

not pressed, and just as sent from Silver Lake.

Setting of machine same as last previous test given above.

2 pockets	-	General Test	-	Dumps	15-16	Ld.Wt.	8.135 gms.
2 "	-	"	"	-	"	15-15	8.285 "
2 "	-	"	"	-	"	16-17	8.055 "

Added more iron to hopper.

2 pockets	-	General Test	-	"	13-14		8.245 "
#17 "		For Special	"	-	"	13	8.350 "
#13 "		"	"	"	-	"	13	8.150 "

Feeding O.K.

Possibly this packs in hopper slightly more than the iron which was pressed, but the general feeding was satisfactory to Archer, and Storms, the foreman.

Yours very truly,

J. P. Miller

MEMORANDUM

EDISON STORAGE BATTERY CO.

July 9, 1914.

Mr. Bachman:-

Following report is of 3 bottles of Iron Mix which Mr. Edison sent over July 8,1914, for loading weights and remarks.

Mach.#704 Center of hopper was divided so as to load only two pockets. Machine feed fingers open full.

#1- Sample- A	pocket	dumps =	10	Weight	- 8.910
	"	"	10	"	- 8.790
Feeding O.K.	"	"	10	"	- 8.830

Feeding O.K.	"	"	10	"	- 9.100
		"	11	"	- 9.230
#3- Sample- A	"	"	9	"	- 9.110
This sample did	"	"	10	"	- 8.730
not feed as good	"	"	9	"	- 8.310
as the other two	"	"	10	"	- 8.570
samples.					

Notebook Series -- Notebooks by Edison
Notebook, N-14-04-30

This notebook was used by Edison during the period April-July 1914. It is the first of a four-book series continued by N-14-08-07. The entries pertain primarily to the transfer process involved in disc record manufacture and to the production of record blanks. The first part of the book contains notes on the problem of wrinkles on transfer plates and possible solutions to this problem. The entries describe experimental transfers made according to different production schedules, with various varnish compounds, or with differently prepared transfer plates. Several notes indicate that many test results were invalidated because a mute was mistakenly left in the phonograph used to test records for quiet surfaces. One entry toward the beginning of the book relates to the solution used in the electroplating processes involved in disc record manufacture. Entries in the middle and end of the book describe the production of experimental blanks and transfers and experiments to improve the varnish. The last entry establishes a new "standard varnish." Employees Jonas W. Aylsworth, Charles Dally, William W. Dinwiddie, Archie D. Hoffman, Charles W. Luhr, and Sherwood T. (Sam) Moore assisted Edison with this work. The front cover is labeled "No 1 Disc." The pages are unnumbered. Approximately 135 pages have been used.

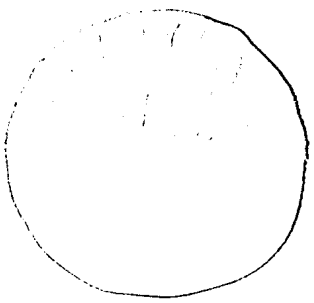
April 30 1914

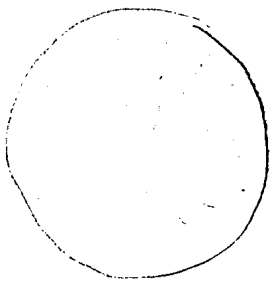
Disc Expts

RO is due to Varnish –
It has taken 3 yrs to find
Thus can only get it when
get blank perfect coating
Thoroughly by Rubber pad

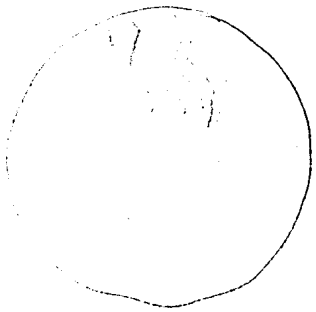
The Var in drying wrinkles,
generally radially –
but ~~[illegible]~~
~~[illegible]~~
~~[illegible]~~ so far the
thick part of Varnish gives
most wrinkles –

+ these wrinkles give sound
~~[illegible]~~ print, the wrinkles cannot
be seen in record of
print but can only
The wrinkles are out of





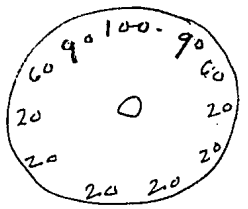
Slight show of wrinkles



Dec 30 1914

hear when playing record —

If a Record shows a Run out say call RO 100% surface - it will be like



There is going to be a very difficult problem to solve, the veneer next to plate is very much affected the outside is dryer as stuff goes off there always leaving some underneath,

Nearly Every transfer plate have these wrinkles on it not one is free of them

Apl 30 1914

By staining with ½" white
Arkansas stone, the tips of
the corrugations are very sharp
by staining down the they
disappear, the RO penetrating
disappears —

These corrugations cannot
be seen in micro —

We tested the pressure in
receiving on plate —

The transfer given the
RO - Evidently wrinkles
show them very much
weaker than on plate

Oct 30 1944

then eleven percent They show them very much weaker —

To fix —

1 = Rig up needle + stone pumice + etc + Tone them off

2 = How Varnish so they do not occur

3 = Dry Varnish so they do not occur

4 Get low viscosity Varnish Rec + they occur

5 = Double flow plate

6 = Put something into
Change Vapor Tension

7 Dry in Vacuum

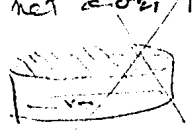
8 Bake to rubbery point 160
+ press quantity on precured
steel plate or glass at 120°
Take off pull + Jab + Run
Oven hequal - Can do very
quick -

9 = Put Vacuum on by spraying
so Alcohol dries as You press
do it by machine +
stretch for all Vapor -

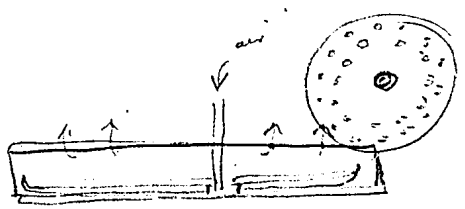
10, Dry little Amyl Al or Acelate Amyl. to stop drying surface - Two Coat,

11= Flow a very thin preliminary flow of thin Varnish 3 times or twice the celeaning dry + then flow Lacquer or Varnish -

12 Let it dry with Cover on wicker + Mosquito net over Top



13. No Vac



14-

cloth all over
4 Blow air
against no cobwebs -

15- Change the schedule of Rumm Oven, stoping draft so it like old way leaving Cat. Vapor exhaust - so can not to dry top. or front

16 Flow 25 cc Reag V dry 1 hour then 250 cc water,

17- Add to Each ~~285~~ grams of Vermiculite, 14 grams Magnesium

18 Ditto 28 grams Magnesium

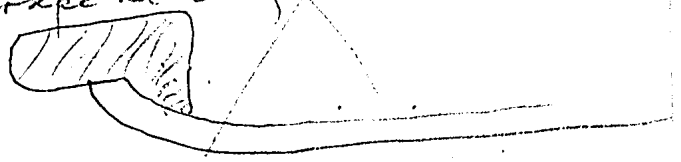
19- Trichloroethylene 28 grams —

14½

Note – Cracked brushed over a well wet dried plate, take out wrinkles after 1 hour in air warm enough to touch back of hand comfortably but RO – This is easily Cured These plates were 24 hours for dried plates ready for oven too soft to stand enough –

20, very fine Light ~~pressure~~ that will not pick those Varnish Lake around edge, 2 or more coats pulp in Bath to keep dissolved coat a few minutes after flaming –

21 – flow plate coat pulp from corner scrape at Edges –



Scrape –

22 = ~~Rub~~ Rub a little Assume rag around Edge –

No reaction or Pure

The Chemicals on Vacuum that gave least or no RO is

365 5% Pararosaniline Acetate No RO

382 - 5% Acetate Buffer "

473 - 3% 5% 12% Parachloroaniline "

455 Alkali Blue 6B 5% "

May 1 1914

367 cc Vermont Coal Tar Test with Para in —

367 Para Rosaniline with 14 grams of dry Ferric Chloride in —

367 cc Vermont Coal Tar Test with Para Added in 1 of 6 7 grams of dry Ferric Chloride —

~~365~~

367 - cc Vermont Coal Tar Test with Para put in - 8 grams of Parachloroaniline —

— Yellow Eosin flow + No waves

Phenolsulphonic alone in
Varnish to the usual Parts
as regards – gives after 6 mths
230 Fahr a pretty light yellow
transparent Varnish –
apparently no change of
Refractive Index – Hardness
Coherence Adhesion
(Chemical Equiv) Unchanged – It will
Dry light

Transferred 2 pCatechol OR
Pyrocatechol & the Triacetate OR
Compound – It work Req
No Triphenylmethane –

May 2 1914

367 cc Req Varnish with Parts Pentane in
14 grams of Camphor –

367 cc Req as above
with 28 grams Camphor –

367 cc Req Varnish with Parts Pentane
with 14 grms Ortho – Nitrophenol –

ditto 28 grms Nitrophenol (ortho)

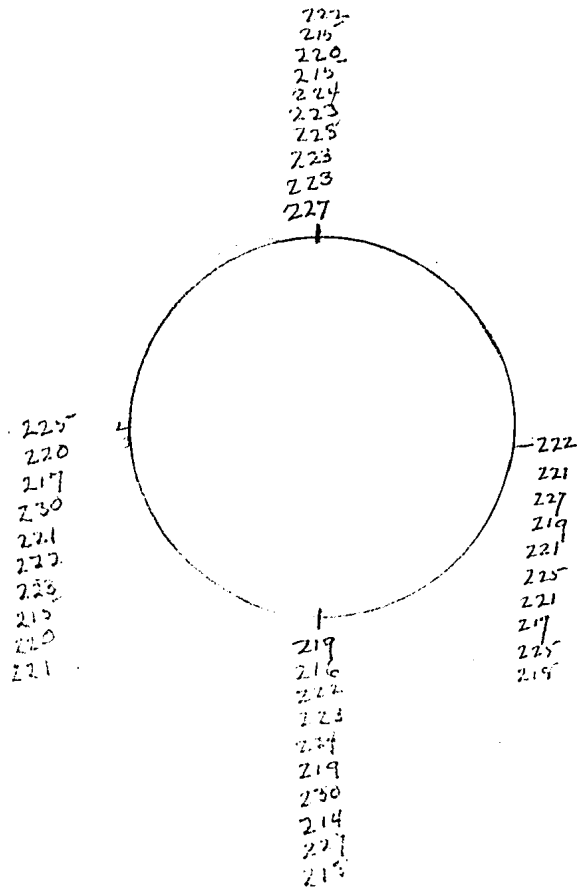
367 cc Req Varnish with Parts Pentane
14 grms Para Dichlorobenzol –

ditto 28 grms " "

367 Reg Var with Para + Penta
with 14 grms Nitrotoluol (para)

ditto, 28 grms "

So far only ones that are free
of Waves & have zoom of Coed
are Phenacocephalata
& the other is Paracollaretandin
both w. Chaud. Para & Penta -



May 1914

Moore reports need Blanks 350 of them Backed only good 52% good — T Blalock Local cost a decent oil spatter on Orange Mountain yesterday had trouble from Chris's Clamped Rocker Arm — It was a nice Oil — Hoffman testing to oil wood spot on — Compared to need Blanks

Schedule run in Dalby's Cyclinder – to get rid of bends + bubbles, by getting all heat out early + just go to rubbery state + heat then long time

Started at 120 Fahr
One hour to reach 140 Fahr
Held 2 hours at 140 "
Then took one hours to reach 225
Held at at 225 for one hour

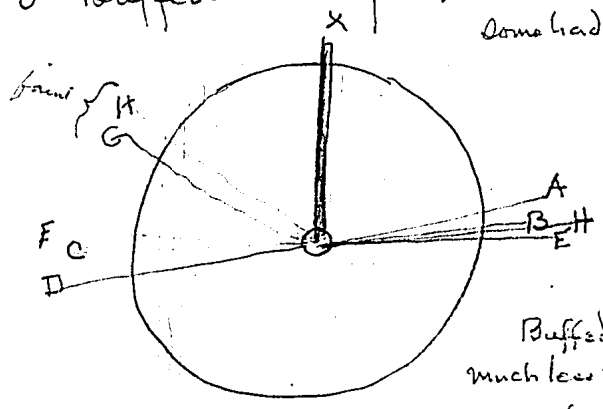
Took them right out in air at 225°
No cracking –

Plates showed No bends, blisters or bubbles except 1 to 3 each plate from dust good looking plates –

Transfers 5 = all OK except one due to very bad blank

This schedule seems good

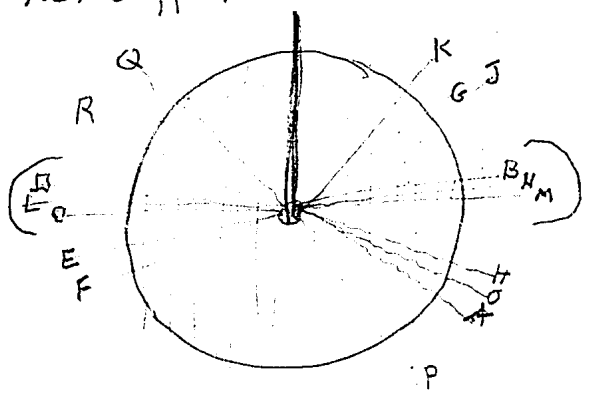
8 Buffed Transfers: Tracked moved
Some had no Runouts



Buffed very much less ROs & surface than not Buffed

X represents grain of plate

Not Buffed



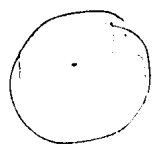
Evidently dust also makes Runouts as well as grain

Paraform Varnish in place 6/4
Run in Oven Rig—
They are soft Cook Click finger nail in— Evidently wants higher & longer heat for Paraform Surfaces Even but ask 1/2 high surface —
Will Transfer— Buffer Print on tracked needed —

All Paraform plates Stuck on Transfer— Not heated Enough— To harden —
Paraform is a high temp long Heating Hardener

Dally Selected 22 plates

That didn't show straight grain of metal



had none of this -

Used reg Vermuth Reg Backs

Dally schedule

Transferred to Practical —

ACC & R — Very fine velvet surfaces — of the 21 surfaces (1 surface had rag plate)

14 had absolutely no Run Out — that could be detected by horn on a tracked blank

One had V RO very soft.
3 " VV- "
3 " VVVVV hardly hear.

This seems to prove that there is unequal shrinkage due to lines on metal — one way shrinks Easy opposite no shrinkage —

We are now getting rid of the Mill Roll

Marks would furnish an surface
to Circular and any Relative
Marks will be Multiplied
x(150 Words of the Record

Not good — The photos had a
White on it + I destroyed
it, it got moved + produced
these fine records when
removed the backed
records had pitting
surface + irregular
RO

Remarkable -

Last week Daddy had
some plates polished +
typed up. These had very
Warwick put on the
surfaces were very good
but some run outs — The
irregular plates + Vera had
fair surfaces all had
strong Run outs
about the 30th Daddy
had Luhr make some
plates with the straight
Mike roll marks ploughed
out + polished circularly
they Vera cuts These
plates had a remarkably
smooth surface Edison
Could scarcely hear + no
run/outs, This Edison
attributed to his hearing
gone bad, Daddy & Carmen
The test surface was
faint, We duplicated

MG

Mute wasn on

Then week seq Van again
& dec no rain but general
surface Edwin could detect
heat

But Dacey retrieved
pounds from very bad
streaked places,

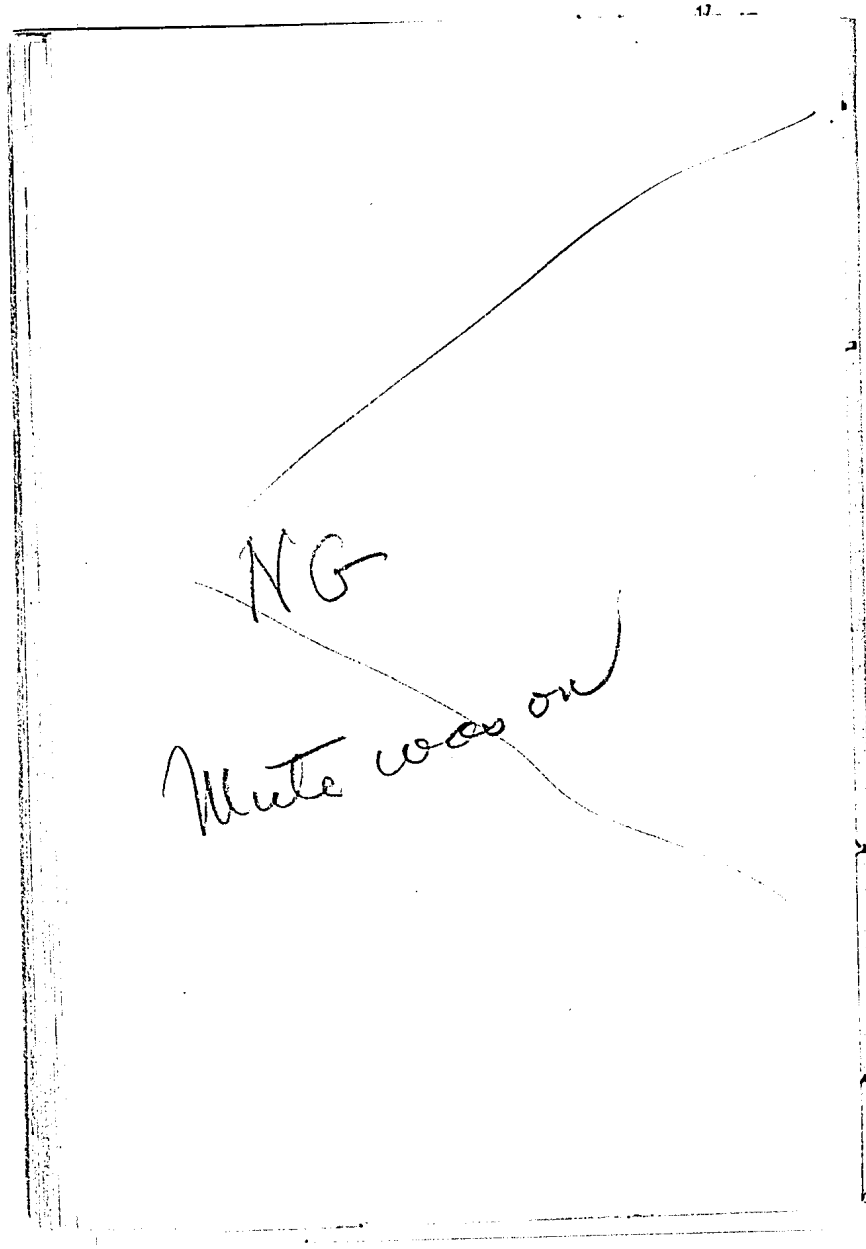
& surprising to say
the general surface of
this was fast not quite
as fast as the standard
plates & although there
was rain only they were
also very fast 3 or 4
times faster than the
same standard test were

Now the only change
we have made is that
on the 28 & believe we
changed developer
Ovens & made harder
transfers & on the 2nd
of June we changed

Doubtful on account of the Mute

Schedule on the blanks XX3 —

Apparently the change in cover Schedule has improved Surface ~~Run~~ Run Outs although the places were little cracks which should have been Level & have RO are put on blanks which both Covers blanks have schedules



Changes, Better surface than these are impossible They are perfect even with adjustments they are Comedy perfect, What caused it,

OPEN or key 6 take back going to or new block the Return Connected on on XX3 or 6 ch = Run it down

I took 74 cracked records from sorting board just as they came from pressing process There was 43 times —

By seeing how many of each times ascertaining Matrix numbers it is evident that records have much to do with Cracks, for instance Kathleen Harriman has highest number 5 - but only 2 matrix numbers were alike — Guess can keep this line of research although its queer that with 160 records on board, there should be so many of same times,

big crack ball runs out or in according to direction of Cracks —

872 Vanmeter

1200 MP Crude cream SR
34 gm. phenol
94.3 " 6/4 —
6% Pentin (6 used with steam)

+ 873 Vanmeter —

Cold Reg Except used MP Cresol & Paraphenylenediamine —

Cloud + baked = all Cracked bad, Too much Paraphenylenediamine 6/4 Condensed too much Wants lean 6/4 —
leave flecks + Very brittle stuff —

Tried MP Cresol again. 6 7 8 9 + 10% 6/4 — Work + workout Para, —

225 Take in oven dont Condense Enough — Worn transformed. 15 min hot at 100 C by accompident They were hard nearly as Tan as Reg —

I think MP Cresol can be made to work on Veneer — it works OK in powder —

Ortho Cresol with 6 Pentin 2 para + Reg Amount 6/4 dont harden in oven & Even when transformed it melts + runs all away There may be a mistake in 6/4 but I dont know how to put it in —

We find that Otto Cresol (German) dont knocked with 6/4 in transforming, melts + runs off -

Meta Para Cresol from Bayway Chem Co, Condenses to a Resin

But it reacts Curious —

35% formaldehyde will plasticize wood or resin — + that is soft + Clear + dehydrated + it works good in powder blanks — But 40 45 & 50 % formaldehyde dont give any greater yield 75% but goes off — I Heat only 35% or perhaps 30% formaldehyde Can be used —

40 of WP gives 30 of Resin — using 35% formaldehyde

Cooling 10 Cents Lb for resin Even if the Excess Coming down in dehydrater isnt any good

Varnish for plates —

. With 4% Penta + 1/10% Para the bubbles are too much

With 6% Penta + 1/10% Para There is very few bubbles —

~~With 5% Penta + 1% Para~~

With 5% Penta + 1% Para

It makes a fine flowing Varnish but yet, dont thicken but little in 20 hours — do ok using 7.9% 6/4 —

I now make New Standard Varnish —

6% Penta

8% Para — 8/10 TH %

8% 6/4 —

Notebook Series -- Notebooks by Edison
Notebook, N-14-06-09

This notebook is a continuation of N-13-08-25.2. It was used by Edison and Peter C. Christensen during the period June 1914-February 1915 for a sequence of numbered "tracking tests" to improve the quality of the "white master" records. Preceding the tests are entries by Christiansen alone [not selected] listing various experimental preparations of wax compounds and phenol resins. The notes indicate that an employee named Miller (probably Joseph Miller) worked with Edison. The spine is labeled "Testing #2." The pages are unnumbered. Approximately 50 pages have been used.

402 Drags a little
Temperature 92 Tabs

Better than the other 402 has a very small drag due probably to high temp 92°
Surface not as good as 651 —
Coolers Chip-shade Elec
651 none —

About like 402 chilled
little worse drag —

Tracking Test #101

#655 - Very good almost - perfect, surface of chunk is better than 651

656 - Don't think it — good surface as 655 -

657 - Drags little -

Drags Bad -

659 - About perfect, just worse than best surface
651 - 84° Falls Condition chips -

660 - Shade of Drag -

Tracking Test #102

661 Not homogenous - ingredients don't mix -

662 - Just little poorer surface than 651 but else good - no drag -

663 - About perfect no Elec condition Chip. fine surface only broke of standing ball -

664 Drags -

665 - OK perfect, ordinary depth Tracking chips is brown paint + perfectly Conditioned Even way below knife Chips are 1/2" Long

Tracking Test | 103

666. good but not quite as good surface as 665 but consistent Clip perfect Like 665 —

667 — about same as 663. slide more because of Ball —

668 — Just same as 665 — good

669 — Same as 665 good

670 not quite as good as 665

(illegible) Dragged & fogged Elec -

(illegible) Bad surface - chip not continuous, thunk at shank Elec

687 Elec surface not very good

Note -

Tracking Test 106

683 · all short chips - fogged. Curious - scarcely any chatter marks goes to knife w some Elec

684 Bad fog - No chatter Mks - Chip 1/16 long, w some Elec

685 Very Bad fog -

686 Bad fog

687 fogged - Drags

688 Very Bad fog

689 fogged

690 fogged

Tracking Test 107

Muddy tinge of fog

Very good - Continuous Chip, not Elec - This acts is nearly just as good as 651 - ~~Foggo - Considerable~~

~~Foggo Considerable~~

- Perfect, absolutely Non Elec

Drags - Too high temps for these Conditions -

Drags a little, temps to high 95° -

Real quite as fine surface as 693 - deep tracking Chips not very long - - as this long Chip has slightly attenuated tip backend -

Tracking Test 108

Matted - some drag temp 76° -

698 Poor grain - not Elec, -

699 - Better surface than 698 - matted grain - not Elec - pretty good cut, probably can be made better -

700 Much better than 699 - Continuous transparent Chip rather deep cut, probably wants more Carnauba -

705 - good = VERY

Tracking Test | 109

706 Surface not homogenous — Chips bunch-clump not Elec

707 Chips bunch-clump Surface not good,

708 Not good surface

709 Perfect - Very fine grind Chatter marks clean cut like rag way - Not Elec Chips bunch + twine around — where ball goes makes surface shade bad but good surface Very fine

Tracking Test | 110

710 Better than 709 - ball has no effect, Chip bunches —

711 About same as 710 —

Temp 76° Faleu

712 Surface not very fine, goes to knife no amount of chips Chips Spiral + Short - Not Very good slight Elec

713 a little better than 712. Light chip Continuous, heavier spirals Blunt + Shade Elec —

714 about same as 713 —

Tracking Test 111

715 Smelled + Dragged 4q —

716 Dragged 6 ad — Dont like

718 Drags some — Dont like

719 — not quite Condem a slight drag surface not very good —

720 Some drag surface not form

721 Drags — short spiral Chips

722 Drags "

723 Drags "

724 Very poor surface

Tracking Test 112

725 Very poor surface Electric

726 Taller surface Drags some slightly Electric

727 Not good surface slightly Electric

728 Rough surface — deep Chip Formation — Drags slightly —

729 fair surf — Drags little —

730 Surface not good — nearly condem Straight Not Curved Chip short Elec —

Tracking Test | 113

731 Nearly Continuous chip not spiraled surface not fine enough —

732 Bad surface — all needle & chisel Wax composed of two or more things — Need to be separated to get any results —

Temp 80 Feb

733. Drags some — not good surface spiral chips & granules some Electrical

Tracking Test | 114

734 Coarse surface NG —

735 Shade of Drag surface not fine enough — slightly Elec spiral chips — broken Knife Edge — when below Neg Knife edge

736 Drags badly. Surface not fine — Spiral chips —

737 Very fine surface NG

738 Not Elec straight chip — Rough poor surface —

739 good straight chip no spiral surface not fine —

Tracking Test | 115

740 Very Coarse surface NG
741 " " "
742 " " "
743 Surface not good Coarse
744 " " "
745 Drags bad surface
746 Horrible surface
747 " " Drags
748 " "
749 Better but too Coarse surface

Tracking Test | 116

750 Bad mixture Rough —
751 Extremely bad mixture NG
752 Very Rough much better than 751 —
753 Rough like 752.
754 Fair but not quite fine enough grain - smuts a little & not very sharp - Chatters irregular
755 Slightly better than 754
756 Drags —
757 Dont Drag grain not quite fine enough - Like 754 —

Tracking Test | 117

758 VERY GOOD no amnt or drag — full space — get thru out + will be fine — 2 mills

759 Same as 558 but much harder chips short not continuous or as long as 758 — Has same spaces —

760 - like 759 - chips short when deep — if short chips don't hurt it OK but think it will be found too hard + Chips stick too much to reamer.

Tracking Test | 118

761 Drags - Curious — powdery Chips - goes to knife - clearly defined Chatter —

Better make 2 cyl. — for Miller —

763 Not so good as 761

764 Good - clearly defined Chatter - Chips break up — stick to cylinder 2 mills

Tracking Test 119

770 - OK. Condemn chip on light cut short chip on heavy cut - not Elec fine grain - 2 Miller

771 Very fine - Condemn chip light or deep cracking - Chatter like Reg - not Elec - 2 Miller

772 About same as 771

773 Light Cut Condemns - deep cracking powdery. Elec Cylinder - Recoatable Too hard Otherwise OK fine surface, no burnt or Drag Chatter Like Reg Therm 68

Tracking Test 120

774 Heller Chem 773 Condemns Chip to Knife Edge - Surface fine grain Pretty good - 2 Miller

775 Too hard,

776 goes to knife Condemns Chip - GOOD fine grain no burnt or Drag Therm 68 2 Miller

777 Little too hard, chips break at knife -

Tracking Test 121

778 chips Coulmn to Knife. Pretty good grain fine. Very good — 2 for Muller

779

780 — goes to Knife Coulmn Very fine grain — Therm 68 Think it could be great 75 or 80 Slender Coo hard nose Chatter Coke Ring GOOD 24 Mar

781 Best for coulmn chip yet 68 False Coulmn beyond Knife — fine grain surface VERY GOOD 2 for Muller

Tracking Test 122

782 all frosted NG —

783 frosted NG —

784 little raft, a slight blush — no drag or count deep knife Coulmn chip —

785 — NG — bloom on it.

786 ~~Star~~ Pretty good — nick 2 cylinders for Muller — surface not Extra fine

Tracking Test | 123

787 like 786 –

788 Good. Surface not very fine – 2 for Muller

789 Very good – 2 for Muller –

790 Good, too hard, Very fine surface + Cluster wall defined + like Requeen 2 for Muller –

791 Too hard can scarcely go to knife – Clusps break up –

Tracking Test | 124

792 Not so hard as 791 – Contains clusp to knife 2 for Muller –

793 – good – 2 for Muller – good grain

794 good 2 for Muller – good grain

795 – Surface not very good = Contains clusp still to experience Thank the Elec

796 Electrical Test Very good. 2 Muller

797 fair but so little Elec

Tracking Test | 125

799 Surface rq - Rollers -

798 Electrical

800 Electric not very fine grain
clumps -

801 Some Elec - clumps -

802 Some Elec not very fine grain

803 " "

804 " "

805 " "

Tracking Test | 126

821 - Ok but bad mix/sm + surface
not Elec - Knufs OK

822 Bad Mix - all comes off
in powder goes to knufs -

825 - Bad mix + surface - powder
Cut -

826 Bad mix + surface - powdery Cut

829 Drags - Bad mix + surface

Tracking Test | 127

871 Works like Reg but appears harder surface not soft.

864 - rafia surface not quite as good as reg cobalt wax

863 surface NG -

860 Worst on Record so far

858 NG -

882 — Can't hear anything with Listening Leica except when just beyond knife edge 40/1000 knife - its very fine chips always around, no powdery chips

Tracking Test | 128

900 Very good different from all others Chatter marks Very fine finest yet, goes to knife edge so sharp Can't see it, Some fine chips chip

901 To hard Chips beyond knife edge Very fine hard to see if it short chips Very few chatter mark never as good as 900 surface blanked,

Tracking Test | 129

693 - wax #o (Made Feb 16-1915)

Tept of wax 296° F
" " wax 93-
Started with mould cold except center piece was hot ring cold (wax runs) after 16 min lifts bottom joint and then put steam in ring then back top joint —

by shaving it sound very rough wax was very unclean

Tracking Test | 130

709 - was made same as #693
Made Feb 23- 15, (3-)
1 was shaved 25 of Feb
sent to Mr Miller for shaving 26-
he says it is hard to do [illegible]

Notebook Series -- Notebooks by Edison
Notebook, N-14-06-13.2

This notebook was used by Edison and an unidentified employee during June 1914. It contains notes on the process of forming disc record blanks. Entries by the unidentified employee at the beginning of the book provide a daily record of observations from June 3 to June 26 concerning "new process Blank machines" for the production of disc record blanks. The daily record includes information about problems with machines, the number of blanks produced, and the number of men working on various parts of the production process. The following entries, which are by Edison, pertain to experiments made with one of the loading and pressing machines to determine how to apply even pressure on the powder (used to form blanks) with a rubber plunger. Included are notes on the timing, the pressure applied, and changes in various equipment, such as scrapers and planers. There are also notes on problems with the powder and the varnishes used to coat the blanks. At the end of the book are several pages of drawings and rough calculations that relate mainly to the layout of a manufacturing department for the production of disc record blanks. The front cover is labeled "Disc Record." The pages are unnumbered. Approximately 50 pages have been used.

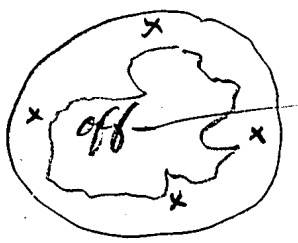
June 29 1914

Experiments on Unit No 1
8 Loaders 4 magnets one
press 4 planers

Expmt to make even pressure
of powder by rubber plunger +
diminish the lifting of the
surface when rubber leaves
powder —

Press has 7/8 inch ram —
usually we use 700 lbs
pressure. This makes lifts
some of the lifts peel off
main body below the planing
line all loaders left
more than edge, Tried 1000
lbs + let it up very slow did
no good, some of lifts went
way below planing off line



+ below
x x Etc no lifts

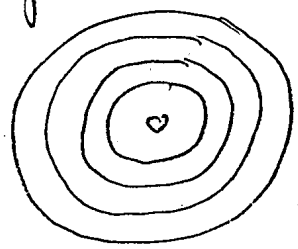
It looks as if Center got very little pressure and trouble was in original loading of the powder too much around edges.

We tried one at 700 lbs laying tin foil on powder & then pressing with the Rubber. This worked OK & powder did not stick to foil but the lefts were there just the same but not so thick putting hand on foil could feel the left as if air was under

We are now running the scraper on packing machine to load in 1/2 a turn instead of one men so powder will not pack so much around edges — no tin foil —

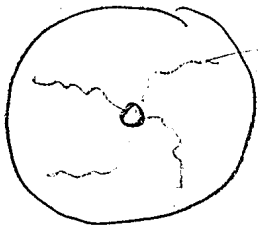
After shaving it seemed more

If its shrinking of the Rubber Cored put rubber on in rings.



Necessarily there would be spaces but am afraid they would get full of powder

Even than the 1 min loading notices on all this



think ½ min is better than 1 minute, but too much lifts —

One packed in 20 seconds appears better than 30 sec

We now try 14 seconds, This seems thin lifts —

Our old 4 leaf planer planed it off good

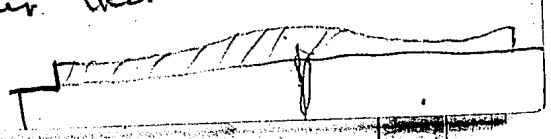
It looks as if old 4 leaf planer at 60 Rev was best

the 8 leafs makes too much air + does something bad shaves come too aflap —

We now change the planer on machine blades to 4 leafs instead of 8 leafs + run 60 — to see how it planes off —

The 4 leaf is much better its going 60 + old one 40, Think 40 Revolution of the planeing scraper 4 leaf is just about Right —

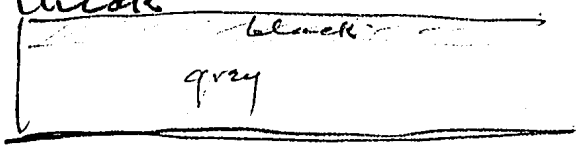
I noticed mine let rubber pressure off too quick + all lifts pulled up in Center Rear



By Keller rubber off slowly
dont left as much —

Tried 20 sec loading + 5000 grams no better I think it not so good as hot + pulls out below the ring

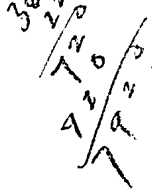
I notice that when ready for Big final press its one thick



What Causes the black

We now make one of 20 sec loading 475 grms + lay one of the old 1/8 rubbers on powder + then put in big rubber press 700 lbs —

1-1



This seems good, more room after planing ~~after planing~~ by finger test There was one or 2 sawdust pull out below ring & fingers fell one or 2/8 of a plane but generally it was taller

We duplicate this with Extra rubber 1/8 thick but put on planer & bring up & let off quick—

Rev of table 2 min 50 seconds
Can put 4 on say 4 in 3 min.
This would be 16 for the
4 Tables in 3 min or
5 per min for the whole
Unit. or maximum of 6600
for 22 hours

The planer Scraper revolves 60 Rev -

With 1/4 rub put on + pressed wkd up + down quick as Could look 20 Sec

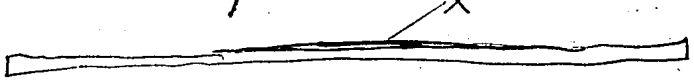
On working quick in process with flat rubber Taking off rubber + then breaking up flakes of the lifts by flat of both hands it planes off good — We must break these flakes up as the planer blades but flakes + break out places below ring where when flakes broken up by flat of hand only powder is taken off by planer + walking breaks below ring + we get smooth surface

9 timed press with press man & one on opposite side they did 10 in 7 minutes but they took off & put on extra rubber & patted with both hands the powder after pressing—

Press man should & may 2 per men & of 2 men on side extra to put & take to. planer table Can do 3 a minute

---

Dence Centers are very hot possibly we can put a piece of rubber on the 1/8 thick



& press center harder or on plunger w press

June 30. 1 am

What is needed is very smooth & very flat 1/8 rubber on packer with the Reg thick rubber on plunger of press

Edison No 1

The lot we are now running there is 20 sec pkg— 1/8 extra rubber on powder then press with Rubber plunger put pressure on & off fast as possible & break up flake by both hands pressing down—

Planer 60 Rev Table 1 Rev in 2 min 50 sec Will transfer 4 pieces 12 at time, they look good, some are a little dark around edge on top

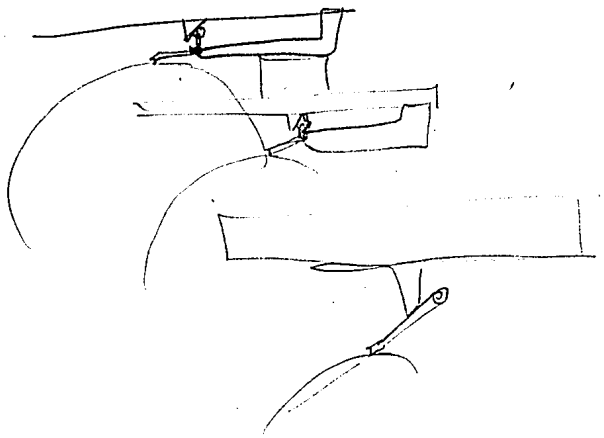
Notebook Series -- Notebooks by Edison
Notebook, N-14-06-00

This notebook contains two undated entries by Edison--a drawing of cylinder phonograph recording or reproducing apparatus and a list of various oils, alcohols, and acids. The entries were probably made in June 1914. Also included is a table, probably prepared by William H. Meadowcroft, of six disc record selections, with data on the number of records ordered and reordered during the period June-August 1914. A final entry by an unidentified experimenter lists four lots of chemicals. The pages are unnumbered. Only five pages have been used.

Only the Edison entries have been selected.



Gasoline
Benzine Pet.
Chloroform
Carbon Tetrachl.
Ether
Ethyl Alcohol
Methyl "
Acetone
Benzol
Glacial Acetic
Nitric acid
Hydrochloric
Gasolene
Kerosene
Paraffine oil
Carbon Trichloride
Amyl Alcohol
Carbon Bisulfide

Notebook Series -- Notebooks by Edison
Notebook, N-14-08-07

This notebook was used during the period August-September 1914. It is the second of a four-book series, preceded by N-14-04-30 and continued by N-14-09-30. All of the entries are by Edison, except for some small notations by Sherwood T. (Sam) Moore. Many of the entries relate to the transfer and printing processes involved in disc record manufacture. Included are notes describing results obtained with various experimental varnish compounds. Also included are entries on the synthesizing of phenol (one of the ingredients in varnish) from benzol. These experiments were necessitated by shortages of chemicals formerly purchased from Germany. A notation by Edison complains that he was "Forced to this improvement by the War -- Thus science triumphs over art." Also included is information on the amount of carbolic acid on hand as of August 26, 1914, and the cost of chemicals from the General Chemical Co. Additional entries pertain to experiments by Charles T. Dally on patching discard records (cracked or not filled) with varnish and to distillation experiments by Jonas W. Aylsworth and William W. Dinwiddie. Entries toward the end of the book include an extended description of problems with varnish, as well as tabulated results obtained with experimental varnish compounds in July-September 1914. These results include notations of the varnish lot number, the weather, and the percent of successful transfers. The notes indicate that Archie D. Hoffman assisted Edison with his experiments. The front cover is labeled "No 2 Disc." The pages are unnumbered. Approximately 150 pages have been used.

Thermo Resin w/ Wood Pulp 60

Sept 22 - We have been having very poor results since about Carson on Labor day - Up to 5th Treatments were averaging 88 to 90 + pounds 85 ammonia then about Carson + did nothing for 4 days when started up, treatments only 50 to 65% + Ex-Mississippi number of pounds by means of our Records could not account for pounds it was the result of a big batch we had - The batches last more than a week - they are kept hot all the time + Each day We take out as hot as we want

Thinking that perhaps Ferric Chloride was lacking in Penta I made batch Varnish 10 gallons + made 300 treatments Containing 1/4% of $FeCl_3$ to 100% of Resin - The results were Remarkable and only got 16% and not all pulled out, at the same time I made

this Expmt I changed perhaps it wanted free acid the Penta always has free acid so I used 6 ml penta as with $FeCl_3$ but left that out & added 1/8 of 1% to 100% of Resin + 6 ml Cracking 300 Transformer oil 5% of only one piece out would have got 100% yield but there were some cracked wares due to bad flowing of Varnish so this Expmt Rheem 10% Wasn't free acid I used HCl

We changed the old leaf & started used to catch up Penta & then is working OK 85% it has free acid as Hoffman wanted to use 3% of acid to get rid of Chalking they put in it at Mill & Chem Wash out the acid - He uses HCl in Porcelain lined Kettle

After he gets them washed out the acid, he uses it but there is some acid # H_2 will also keeping it melted the whale week & will only heat up to soften while he takes what he wants & then put cover on & let it cool down this prevents the penis from being cooked to death

Tonight I took some of the Penis just as it comes from whale & found it full of acid also very much grow

I find that for hours you can keep it just warm & stir pickled in water & the now still comes out it seems to have an unlimited capacity for holding ~~H_2~~ $FeCl_2$

If the now is to be got out must have a strainer run

by power + frequent changes of water – It's not necessary to boil the water as Trichlorophyl comes off –
I have told FWA to tell Mell stop putting Lime in Penta if they ever did – its not necessary Old penta worked good + had it have lime in it's sauce it was used to diminish the acid so they could stop it. –

Also Tonight. FWA said if I put acid in the alcohol the 6/4 would give off its ammonia + free the formaldehyde I find that neither in alcohol or water, saturated with 6/4 does the addition of HCl give slightest smell of formaldehyde

Ppt of 6/4 is dissolved in alcohol that the addition of HCl throws down hair like Crystals of a salt. The thought that this was MethylCl, but on heating it enormous Volumes of smoke comes off which is pungent & a large residue of Carbon remains —
The Crystals are pure white that comes down —
Some of the Crystals are soluble in alcohol & do not come down on Evaporation gives white residue & had an Excess of acid —
Evidently 6/4 combines with HCl to make a salt very soluble in water but not nearly as sol in alcohol as 6/4 — but on account of large

I find the HCl combines with the Para in Alcohol making it far less soluable but I think the Alcohol is the main reason that it will not precipitate out I will find this out.

amount of alcohol we use, there will be no precipitation,

I have weighed out

8 " 6/4
1/2 " Para No perhaps
125 mlg HCl which is proportion used in Expmt where got good results - There is no precipitate

I now make 2 more Solutions as above

No 2

has same as above but HCl increased to 250 mlg

No 3

Dup increased HCl to 1 gram

By mistake 1 2 & 3 gram alcohol used instead of Denatured

145 grms Alcohol
2 grms Para
250 cc 1/4% HCl

Want to see if 1/4% HCl will precipitate the Para

No Hg used grain alcohol which dont work like Denatured

No 2 on following Alcohol shows that 1 grm or 1% HCl is a little too much as there is a slight residue on filter paper, its brown & must be the HCl combin with para yet I see a few crystals of the white that look like Coq—

It may be an impurity in the Para which is Crude grain

Now using Denatured

No 1—

145 grms Denatured
8 " 6/4
1/2 " Para CP from DeHaen
1 " HCl—

to wet and Test paper

Acts different from grain
no precipitate—

No 1 Continued - The solution is just linked red + no change at any thing Comes down Can see it.

There is no precipitation showing that the precipitation of Green stuff is due to impurities in the Crude Para used by us - it darkens color and is put in but Can still see thru it -

So this proves we can use up To 1% of Hydrochloric acid in our regular Varnish without precipitating anything out

Providing HCl is put in last after 6/4 Para has been dissolved

I think there is more than we need, we used 125 mls out of 1/8 in one pound of the Varnish we got years ago - but of course the para had some HCl in and may have varied but it could be great ~~by~~ I think with para bleached free of more than 1/2 percent of HCl would be enough perhaps 1/4 will do, Will have to try it

We bleached red para from Wyandotte + found no like as clear by 3 wks -

Later No 1 + find on standing precipitates out Bradow sediment just like Reg para

CHJ

No 2 is 145 Alcohol
8 6/4
2 pure Para with
1 HCl –

On pouring on HCl gets black
Cant see thro –

When the Para is in Excess of the acid and above
Nothing Comes out

Evidently the Para should not be entirely neutralized

No 1 still keeps throwing down brown precip
after filtering twice the filtrate gets cloudy

Either the air or some reaction goes on slowly +
Para precipitates out when
acid gradually Exposed Para

I tried alcohol saturated with Ammonia & then put in HCl, had to use considerable but finally white Ethyl Amine smell but like the Ferric Salt needles as when 6/4 is used –

There is very little Insol but with HCl continues with 6/4 it to form a good Compound –
Not nearly as much insoluble as 6/4 but plenty to spoil Example of the Compound – the Trademark of it's able work –

The precipitation from 142 is getting very small but looks as if most in No 1 precipitated + Very little in #2

Made up a Varnish
145 alcohol
10 6/4 HCl Combs boil only about
6 minutes. No pain or Penta
Condenser or boiler plate
quick no gum there is
no doubt about a HCl 6/4
Salt that is as good as
6/4 + Cl used the brown
of Ammonia when completely
May not want either
Penta or Penta - Varnish very
thin -

Seems lots bubbles
+ acts bad -

Sept 23 & 24th Penta now used
tested by us Moore No 2
was practically free from
acid and iron - scarcely
a trace of either, put in HCl
to see if any metallic Fe
there was none, so washed
acid out,

No 1 Edwood is the Raw
stuff from Wyandotte
had lots acid & iron
washed it free = 6
bath -

Penta old dissolves nearly
all in Boiling Petroleum
Benzine & filtered leaves
residue & solution dark
but if bone black used

its a very light tint of red
& OK — Wife like if what
dwt was is what we want

Moore No 2 after formerly
is very much harder
than Edwin No 2

No Lime was in either —

New Balch Pentz.
3% Hcl. leached-Washed free acid has very
little Iron in it - its very stiff Tar

Notes –

Alcohol in Vacuum Varies from
115% To 100% Rean –
To 155% & yet. got good results
so there is no appreciable
bad effects from more or less alcohol
Best about 142% appears
best — This is from all
the data for 2 months, over very
good & very bad periods —

When there is a high percent
of OK transfers, There is from
4 to 10 times more Cracked
transfers than Pull out transfers

When there is a Low percent of
OK transfers – it is just
the Opposite, There are from
4 to 8 times more Pull outs,
than Cracked transfers –
The Cracks don't vary much

Trichlorophenol never tried in Duo Van

It Combines with NH_4 from saturated alcoholic sol of NH_4 to a precip insol in water but sol in alcohol

Trichlorophenol very sol in alcohol

By saturating alcohol with 6/4 & then pouring in strong sol of Trichlorophenol there is no precipitate – it does not take the Ammonia from 6/4 apparently, gives clear solution

Apparently Trichlorophenol will absorb the NH_4 when 6/4 is mixing –

Trichlor is a great & powerful Crystallizer –

Note.

Trichlorophenol strong does not precip Paraphenylenediamin strong when poured into it The solution becomes ~~[illegible]~~ darker – but not very much

None of the ingredients precipitate out Trichloro, 6/4 para,

Even the Trichlorophenolate of Mg 4 does not precip –

Strong sol of 6/4 m cl is precipitd in long silky needles by Hydrochloric + Cheselave not nearly as sol as 6/4. they are not Mg 4 Cl 4 but a true compound with HCl – Dont think more than 5% will dissolve in 145 alcohol

This substance is very soluable in water –

Notes –

I find that Penta treatment after add that Alcohol will take out warm 110 fahr about Will if Phenol pure is added the solute of treatment dissolves but when alcohol is added most of it precipitates out but a large part remains in solution + if filtered off is deep red If now more alcohol is added to clear red solution there is no further precipitation

showing phenol aids greatly to dissolve more penta – if this substance is good then 15% Phenol in Resin or lower will be best then we can use 7% phenol free in the alcohol & this gets more of this substance

CITU

Note

I don't think 6/4 + Trichlorophenol Combine as apparently they Crystalize out seperately but not sure —

The Trichlorophenolate Ntly Crystalizes in pin Cushion rosettes —

Trichlorophenol + Para Rosolic crystalizes together abundantly but not certain

6/4 seems to condense Trichlorophenol slightly —

I note that the Varnish made with Trichlorophenol instead Perit dries slow — also shows tendency to make bubbles —

We need an insoluble Coat of Penta from Michigan — I found if we put pieces phenol in it it semi dissolves, When heated then keep adding alcohol — Keeping almost boiling You can keep on adding alcohol & finally on filtering practically all dissolves & no amount of dilution with alcohol Gold precipitate also — also if phenol Combined with it & then it was put in alcohol — The reason it dont dissolve in alcohol is probably due to fact all the phenol used in Chlorinating part was Chlorinated / Observe the Sol Penta has phenol in it & to this that makes it Soluable = I once tried Penta with 6/4 & found it partially Condensed this

probably proves that there
is free phenol in oil
Petro —
There is a big find —

new 1/2 bags Comp - used
new 1/2 bag till Aug 10
2 bags on 11th since used 3 bags

Notes -

If phenol alcohol Penta residues ~~not~~
used in alcohol alone, bad Rez
Resin added it deadens acorns
as the free phenol of the
resin helps to make it rot—
I mean that which precipitates out on standing after
Also little Resorcinol added
to alcohol aids its rot

It is probably the Resin which
deadens in phenol Benzine
Coats + prevents alcohol
deadening some - If Residues
used in phenol + alcohol —
is treated H of Benzine largest
part dissolves + is precipitated
by alcohol The alcohol is
very red + deadens it now dissolves
more while the Benzine holds
the Tar + floats to top

Might be good way get rid
of Resin Tar—

Notebook Series -- Notebooks by Edison
Notebook, N-14-09-30

This notebook was used during the period September-October 1914. 1914. It is the third of a four-book series, preceded by N-14-08-07 and continued by N-14-10-04. All of the entries are by Edison, except for some small notations by Sherwood T. (Sam) Moore. The entries pertain primarily to the transfer and printing process involved in disc record manufacture and to the Condensite varnish surfaces applied to record blanks during the process. Included are notes describing transfer and printing results obtained with various experimental varnish compounds, which contained different amounts of phenol, alcohol, "para," "penta," and "6/4." Additional entries relate to experiments by Jonas W. Aylsworth to hasten condensation. Inserted into the book are several loose pages of notes by Edison that tabulate some of the results noted in this book. The notes indicate that Archie D. Hoffman also assisted Edison. The front cover is labeled "Disc = 3." The pages are unnumbered. Approximately 125 pages have been used.

Sept 30 1914

Using raw Penta + Washing
it boiling with 2% NaOH and
~~put out for ...~~
then precipitd with Strong
HCl - got and large amount
The Water portion was
then boiled down to dryness
& HCl driven off — after
thoroughly drying
cleaved and dehydrated as
Combustions Manually
& then 16 tenth the KPt-
Ether Empirical as in
Needles -

Adding Equal % to Reg
Var of alkalone Thoroughly
absorbed. The Percentage
of ~~to~~ determined was at 6d
Alkalone 2nd by Benzol -

For July + Aug over ½ of good
Indentures (Green Light) Last
plates (Loaded Sept 4 —
(Then 3 hole Cups (Laflin Smith Gun)

The plates Nearest and 4th
gave 92½ good but those
(Loaded on 8th & up to
date Sept are Very bad)
65@ 75 ½ mostly pull outs

Another Change we made
in Hole Cups used to change
pulling the Varnish in
Blank powder from a pressing
to pouring it in —

Examining the pull outs
in Indentures I find very
faint Cracks & believe
pull outs start at fine
Shear Cracks — if so
then the trouble due to
pull outs is due to blank
not to Varnish, but

Thought this would impossible till I discovered these fine Cracks at every pull a cel— Thick veneer dont work— Varnish is unequaly distributed on powder by pouring it on

Try 2 lots req Var 903 two bottles dewhis — one had Some Alcohol saturated with ammonia put in & the other equal amount Alcohol no ammonia They did not act much different,

Tried 2 with Req Resin in alcohol saturated with ammonia work as good as Req + less Bubbles no pores or ridges thick comes off easier

100 grms phenol 5 grms 6/4 long glass tube in cork left flask upright on hot plate.

Does not show any signs of condensation or thickening after 60 hours -

100 phenol 10 grms 6/4 after 60 hours thickens some + gives a Resin -

100 phenol 15 grms 6/4 60 hours is about right Condensation. Very thick Molasses like + pours all out OK

It could require 16 To 16½ to produce same amount in 10 hours & thick -

100 grms phenol + 20 grms 6/4 fused & went solid in 2½ hours - probably for Very 18 To 20 grms 6/4 should be used

Note, If Formaldehyde 6% added to a water solution of Paraphenylenediamine It gives a very fine bulky precipitate This if dry does not show the slightest sign of reacting or of coming if put right on the hot plate.

Also this precipitate is insoluble in boiling alcohol —

This reaction may account for Para's action in Venereon —

Its real Sol in reaction or Benzol — ? ?

If Paraphenylenediamine is dissolved in alcohol formaldehyde does not precipitate anything But when I add water and the precipitate appears

This caused show that if there really is 22 grms of Free Phenol in Resinol added we ~~should~~ use up 5.3 grams alone for phenol leaving only 2.7 grms to harden the resin —

Note, This Combination is real in Hot Phenol ? ?

But pouring on dish a very slight sediment separates probably impurities in Para — after free phenol smoke stops coming from dish I notice sediment readily dissolves so its OK if it does the reverse

Here is a Cure - Took pure Phenol put in Bottle 6/4 could get in Hot & by shaking - poured out on butter dish right on hot plate

Poured in 2 dishes, in one put in a little para - none in the other —

Both started smoke Green Phenol distilling off —

Soon the dish with para stopped distilling off Phenol, & turned Color & form into a Varnish

While the other. the Phenol all distilled away & left Nothing but Mixed white Crystals of 6/4 in other words

Para in Varnish prevents great loss of Phenol in oven & hardens plates

When put on hot plate crystals redissolve.

Very Good -

This is a very striking & Important Experiment

After ½ hour the phenol 6/4 Para is thick again on hot plate butter dish but does not seem to want to harden Enough, to get more 6/4 in it until a big increase. I Think to use mixture of pure phenol phenol with mixed recrystallisation to get Enough 6/4 in

I will try ½ phenol & ½ alcohol

When ½ + ½ is tried the Evap of alcohol throws out 6/4 in crystal form + its rig — no para —

Dried Phenol only slight alcohol This also throws out 6/4 when para put in Even worse

Think got too much 6/4 —
No I am mistaken it Phenol
Ether crystd out getting cool
by Evap of Alcohol on boiling
right on hot plate open clear

Both with + without para
when put right on hot plate
phenol deposits off -

Another bug with phenol +
but little formalin -
Para precipitates out,

Also same thing when
formol HCl crystals from
pouring formaldehyde into
alcoholic Para, used
in place of 6/4 —
precipitates out even
worse than carbon
6/4 only used

There is no doubt but with either 6/4
or formol HCl - addition of para preserves
95% of the phenol from Evaporating
in little beaker dish right on
hot plate,

6/4 seems more favorable as it
dont precipitate much para
out,

6/4 alone nearly all the phenol 95%
Evaporates + escapes condensation
which a pinch of para in the
Duplicate pair saves 95% +
it recrystallizes —

I note that the formol HCl without
para 1/2 recrystallizes + dont dissolve
+ recrystallize same when placing
6/4 phenol all gone,

I rather think formol HCl is good
without para, perhaps wants
more after + but it may not be
as good as 6/4 with para —
am weighing out to make definite

No 4

25 phenol
5 6/4
20 alcohol no para

All 1 2 3 4 + 5 in dish
on asbestos at 445 pm
in 5 minutes the phenol
in 4 + 5 with para
had crystalized out with
6/4 – whereas No 1 2 +
3 with para were
clear in 5 minutes
after all the Nos 1 To
5 had gone crystalin +
dry from Evap of
alcohol ↗

No 3

25 phenol
3 3/4 gms 6/4
20 alcohol
1/2 Para –

I now put dishes from asbestos
right on the metal of hot plate

No 3 is only one that for last
10 minutes to all liquefied

Phenol is dividing off of alc

It looks like it is going due to
low 6/4 + high para +

At 5.12 or 27 minutes after
pulling on 1 2 + 3 are
clear while 4 is nearly
dry + crystalized + 5 all
phenol practically divided
off –

5

25 phenol

3 3/4 6/4

20 alcohol no para

Nos 4 + 5 are hopeless must have para to hold phenol from coming out in ether

I now take flasks containing Nos 1 to 5 + add 5 grams of water to each

Nos 1 + 2 were solid

When cold No 3 liquid No 4 solid + No 5 liquid

When the 5 grams of water were put in all the solid except 4 became almost instantly liquid & clear phenomenon!

No 4 only lagged, some cry not quite dissolved —

Took all off — 4 + 5 ng

1 2 + 3 solid & clear looks good — No wonder we need para —

at 530 pm Oct 1/14 pour 1 to 5 with 5 grams added

Water (The mix – butter plates on 1/16 thick asbestos on hot plate –

All but No 3 went crystalline at 5 45 put right on hot metal –

Not as much smoke of phenol off the water Expt.

~~0/Bar~~ Water Expt 1 2 4 3

Clear & resined –

4 crystals & phenol apparently dissolved off – 5 1/2 Cry 1/2 liquid took off – acts about same as of no water, not quite as good, and amount of Resin is less say 20% No 2 being greatest amount. This shows that Water is not dangerous apparently –

Remember Water was put in after I had poured one set plates + therefore must be equal to 7 grams or 35 gram of water to 100 alcohol.

I now add to the balance of the mixtures in 1 to 5 after having poured out 2 rounds – or about 1/2 I add one gram of Penta which I dissolved out of E I penta by alcohol which was original Rees Penta remarked or treated by Hoffman –

The phenomenon about this Expmt is that I cant see any smoke from any it appears as if Penta held phenol but possibly alcohol has now gone + must have gone crystals + not Clear + Water cell now

stand to go off & will get Smoke & phenol will go —

It may be an asset if there is much water in Alcohol & Resin — that the water will hold back ~~the~~ phenol from Evap sat'd to temp (wont rise above 212 until the gone & by that time phenol will be more syrupy & non Volatile

It clears on all but #4 after water gone & smoke is very small compared to the others, 1 & 2nd Rounds,

It certainly looks as if Penta helped Para to hold phenol in Varnish till it got non Volatile

Took 1 2 & 3 off Thick room not fused — Thicker than Either Round 1 or 2 — & Best yet yield slightly better than any —

Even No 4 without para is a resin but more than ½ probably ⅔ has distilled off — towards end it bubbled frothed, No 5 is smoking but unlike the other 2 stages is clear — took No 5 off no resin — yield comparable to #4 — etc —

3rd Round (Penta) — 1 & 2 hard — #3 soft — Very black

Apparently anything that will hold phenol from distilling out of resin till it gets to the

Non Volatile state is good—

Paraphenylenediamine is poor, Excellande the best substance its action is wonderful

Next Comes Penta. which is only moderate as compared to Pheni,

It may also be allergenic beneficial—

25 grains Phenol -

5 " 6/4

1 1/2 " Penta

1/2 " para

9-7-10-6-8

Notes, ~~Same~~ 6 7 & 9 + 10 on asbestos 11 pm —

I should measure off the amount I put on each plate,

9 10 + 8 right on hot plate dont crisp or smoke + are perfectly clear at 11 12 -

7 is crisping some + Crystals at 6 is crisping slightly + smoking (a bit).

Remember I put no alcohol on the Expmt like I had on 1 to 6 -

at 1120 pm -

9 10 + 8 are seconds Thick — 8 is the Thinest

7 still Crystals - 6 clear - no ring.

as I had difficulty to mix 7 + 6 - 7 being impossible + 9 10 + 8 mixed OK -

Evidently Penta Para Causes 6/4 To dissolve good + in their absence — 6/4 Crystallizes out.

This is another important fact + explanation;

as I had more trouble with 1st Lot with Para ~~to~~ get all the 6/4 To dissolve although Para present I have had with this Lot, Evidently Penta helps To dissolve 6/4

Oct 1/14

Took them all off at 1135 pm

I noticed when I was heating this bunch with corks in two of them blew corks out although there was no alcohol — There must be some reaction making vapor or gas — probably alcohol in the paraffine but it was small —

I note that No 6 with no para is the hardest resin while 9 10 & 8 are much softer, that must be due to fact that the 6/4 dreadnought dusted off like it did in No 6. which having much less phenol got a bigger dose of 6/4 & got harder

No 7 is not a resin but a mass of crystals probably 6/4 (where as #9 had as much 6/4 as 7 gives big crystal resin

Same as 6, 7 & 9 & 10 — but to remaining material added 10 grms alcohol to each — all clear

8 9 10 7 6 in order

8 is 1st to boil — on 12 Midnight on alcohol —

When alcohol is used it creeps badly up to 2 edge of dish — not as when no alcohol except some Crisp where no para used

At 1207 or 7 min after pouring in dish the asbestos 8 & 9 are rough as well as 10 8 & 9 about same 10 not so much

#6 No rain - a drop on cold glass shows phenol crystals
+ #7 is still all Crystals
phenol + 6/4 Cry

at 1225 am take off -
8 has no bubbles
9 some
10 the most
7 all Cry
6 clear no bubbles

There is doubt about which is 10 as I have 2 #8's

7 all Cry + Smoking Even after take it off

at 2 pm 8 9 + 10 are liquid with flasks
(12) The remainder not read while 6 + 7 are Crystalmt Sol

Emulsified Hoffman Resin sticks is hard enough to stand the Reproducer all that it needs is to fire it just a little to stop brittleness —

Think we want to keep our 6/4 low + use 2% para
4@6
+ ~~5~~ of good Penta of Even quality -

Assembly 7.5 @ 7.6 6/4 with 2 para will do, Even low we have = Expect Coming Down with less than. 7.8% 6/4 -
as 7.8 gave 70% good Transfer with only 1/2% Para Think 7.4 will do if use 1% Para

11-12-13 Remarks —
Only # 11 was clear
12 & 13 had lots undissolved
Crystals 12 the worst
big sediment,

Evidently para is incompatible with X — precipitates

after pulling on metal
of hot plate / No 11 has brown
tarry Crystals —

Notwithstanding Crystals
Etc all have formed resins
at 1.35. rather thin —
& apparently all the Crystals
are disappearing — & solutions
getting clear,

See next page

Notebook Series -- Notebooks by Edison
Notebook, N-14-12-03

This undated notebook is a continuation of N-14-04-26. It was probably used during the period August-October 1914. All entries are by Edison, except for several notations by another experimenter, possibly Frederick P. Ott. The entries pertain to experiments aimed at the rejuvenation or "regeneration" of used storage batteries. Included are the results of tests performed on cells constructed with different regenerated components, primarily old negative electrode "pockets" reconstructed with treated iron or formed using different crimping dies. There are also a few experiments that involve regenerated positive electrode "tubes" made with treated nickel hydrate. Most of the experiments bear sequential numbers, 241E-382E. Some of the cells produced in these experiments were apparently transferred to the Edison Storage Battery Co. at Silver Lake for continued testing. Their subsequent performance is tabulated in N-14-12-14.1 (see Notebooks by Edison and Other Experimenters -- Storage Battery). Inserted into the book are two memoranda by Walter N. Archer and several loose pages of notes, probably by H. H. Smith. They date from the period August-December 1914 and relate to regenerated iron and nickel experiments being conducted for Edison. The front cover is labeled "Regeneration No Two." The pages are unnumbered. Approximately 160 pages have been used.

No change better than Replicate

294 - Reg green. hot soaked 48 hours in hot Concentrated Nickel Chloride - both hot when put together no Excess Liquid (12) no free Liquid but slice very moist outside each particle.

Dried -

Then put in 20% (NaOH) 24 hours -

Then washed perfectly free of Cl as tested by Ag Nitrate -

Both sent to Rochester with instructions for Analysis to Heake -

(12) 294 & 295 -

This is Hercules aluminum Sulphate Big Kat crust up by Miller —
Skin sample wrist work
Jig: Hard Salmonid work
Lithia hydroxide —
2000 lbs pressure in Dure mould in Rag 12" Ream Dure press
It was not loaded on plate It got just barely covered —
Used 2 lbs to Each Dure
As loaded covered nicely 2/3 was hard Enough to crush Easy Chalk, to work
It Looks four Coat Commercial fence, in —
Miller is to Load 2 buckets Each Kind, & Clean acid balance to Works, to test if it frades OK —

[ITEMS(S) FOUND IN BOOK]

August 13, 1914.

WNA-16-4349

Messrs. Edison-Bachman-McClain-H.H.Smith and file-

Request Mr. Edison S.O. #4867-E
Make up 2 A-4 cells.

#704 Mach. Special Iron Mix Exp. #2109

Dumps 15-25) A pocket
Weight 7.768)

Remarks- Gritty greyish iron, very bulky pockets and iron both became slightly warm.

#824 Ni.(OH)2 = .02853 per dump
Lot 266 Ni.Flake = .00371 " "
Dumps per tube =313
Weight " " =10.685

Serial numbers from H. H. Smith.
S.P. #60 and S.P. #61
Sent to Research Dept. August 13, 1914.

W. N. ARCHER.

[ITEMS(S) FOUND IN BOOK]

August 13, 1914.

WNA-16-4348

Messrs. Edison-McClain-H.H.Smith-& file:-

Request Mr. Edison S.O. #4813-E.
Make 4 A-4 cells.

2 cells regular factory stock
2 cells special and use pocket stock which has been ground
#729 Mach. #2989 Iron mix

Dumps 12-16)
Weight 8.265) A pockets

Remarks loading O.K.

#824 Ni.(O.H.)2 = .02853 per dump
Lot 266 Ni. flake = .00371 " "
Dumps per tube = 313
Weight " " = 10.583

2 regular cells factory serial (#8382B & #8383B.
2 special cells ground pocket stock serial numbers from
Mr. H.H. Smith. S.P. #56 and S.P. #57
Sent both sets to research August 12, 1914.

W. N. ARCHER.

PUBLICATION AND MICROFILM COPYING RESTRICTIONS

Reel duplication of the whole or of any part of this film is prohibited. In lieu of transcripts, however, enlarged photocopies of selected items contained on these reels may be made in order to facilitate research.

A Note on the Sources
The pages which have been filmed are the best copies available. Every technical effort possible has been made to ensure legibility.

FINANCIAL CONTRIBUTORS

We thankfully acknowledge the vision and support of Rutgers University and the Thomas A. Edison Papers Board of Sponsors.

This edition was made possible by grant funds provided from the New Jersey Historical Commission, National Historical Publications and Records Commission, and The National Endowment for the Humanities. Major underwriting has been provided by the Barkley Fund, through the National Trust for the Humanities, and by The Charles Edison Foundation.

We are grateful for the generous support of the IEEE Foundation, the Hyde & Watson Foundation, the Martinson Family Foundation, and the GE Foundation. We acknowledge gifts from many other individuals, as well as an anonymous donor; the Association of Edison Illuminating Companies; and the Edison Electric Institute. For the assistance of all these organizations and individuals, as well as for the indispensable aid of archivists, librarians, scholars, and collectors, the editors are most grateful.
